

**Local cohomology**

Speaker: Anton Leykin

Scribe notes by Jeremy Martin

We work with the following objects throughout. Let  $\mathbf{k}$  be a field and  $R$  a finitely generated,  $\mathbb{N}^n$ -graded  $\mathbf{k}$ -algebra, i.e.,  $R = \bigoplus_{\alpha \in \mathbb{N}^n} R_\alpha$  with  $R_\alpha R_\beta \subset R_{\alpha+\beta}$ . The motivating example is  $R = \mathbf{k}[\Delta]$ , the Stanley-Reisner ring of a simplicial complex  $\Delta$ . Define

$$R_+ := \bigoplus_{\alpha \neq 0} R_\alpha$$

the so-called **irrelevant ideal**. Finally,  $M$  will be a  $\mathbb{Z}^n$ -graded  $R$ -module, i.e.,  $M = \bigoplus_{\alpha \in \mathbb{Z}^n} M_\alpha$  with  $R_\alpha M_\beta \subset M_{\alpha+\beta}$ .

1. DEPTH AND COHEN-MACAULAYNESS

**Definition 1.** An element  $a \in R$  is called a **nonzerodivisor** (or *NZD*) on  $M$  if  $m \in M$ ,  $am = 0$  implies  $m = 0$ . Equivalently, the map

$$M \xrightarrow{a} M$$

given by multiplication by  $r$  is one-to-one.

**Definition 2.** A sequence of homogeneous elements  $\theta_1, \dots, \theta_s$  is a **regular  $M$ -sequence**, or  **$M$ -sequence** for short, if  $\theta_{i+1}$  is a NZD on  $M/(\theta_1, \dots, \theta_i)M$  for  $i = 0, \dots, s-1$ .

**Definition 3.** The **dimension** of  $M$ , denoted  $\dim_R M$  or  $\dim M$ , is the Krull dimension of  $R/\text{Ann}_R M$ . The **depth** of  $M$ , denoted  $\text{depth}_R M$  or  $\text{depth } M$ , is the length of a maximal  $M$ -sequence. It can be shown that every maximal  $M$ -sequence has the same length.

In general  $\text{depth}_R M \leq \dim_R M$  (since any  $M$ -sequence of length  $s$  generates a height- $s$  ideal of  $R/\text{Ann } M$ ). Equality is an important “niceness” condition which gets its own name:

**Definition 4.**  $M$  is **Cohen-Macaulay** if  $\text{depth}_R M = \dim_R M$ .

2. LOCAL COHOMOLOGY

Define the **torsion functor**  $\Gamma$  by

$$\Gamma(M) := \{u \in M \mid R_+^n u = 0 \text{ for } n \gg 0\}.$$

It is routine to check that  $\Gamma$  is a covariant, left-exact functor. That is, a map  $f : M \rightarrow N$  of graded  $R$ -modules induces a map  $\Gamma(f) : \Gamma(M) \rightarrow \Gamma(N)$ , and if  $f$  is injective then  $\Gamma(f)$  is injective.

The  $i$ th local cohomology functor  $H^i$  (more precisely,  $H_{R_+}^i$ ) can now be defined as the  $i$ th right derived functor of  $\Gamma$ :

$$H^i(M) = R^i \Gamma(M).$$

That is, one may calculate  $H^i(M)$  by taking an injective resolution

$$I^\bullet : 0 \rightarrow M \rightarrow I^0 \rightarrow I^1 \rightarrow \dots,$$

applying  $\Gamma$ , and defining  $H^i(M) := H^i(\Gamma I^\bullet)$ . (See a textbook on homological algebra for more details.)

**Lemma 5.** For all  $i$ , the modules  $H^i(M)$  are  $R_+$ -torsion, i.e., they are killed by some power of  $R_+$ .

*Proof.* By definition of  $\Gamma$ , every module of the form  $\Gamma(N)$  is  $R_+$ -torsion. In particular, if  $I^\bullet$  is an injective resolution, then every  $\Gamma(I^i)$  is  $R_+$ -torsion, so the same is true of the cohomology modules of  $\Gamma(I^\bullet)$ .  $\square$

The local cohomology functors are useful because they detect depth and dimension. Specifically, we have the following fact.

**Theorem 6.** *Let  $e = \text{depth}_R M$  and  $d = \dim_R M$ . Then:*

- (1)  $H^i(M) = 0$  unless  $e \leq i \leq d$ .
- (2)  $H^e(M) \neq 0$  and  $H^d(M) \neq 0$ .

*Proof.* We'll prove only (1), which is the case we really need. We proceed by induction on  $e$ .

If  $H^0(M) \neq 0$ , then every element of  $R_+$  is a zerodivisor on  $M$ , which is exactly the statement that  $e = 0$ .

If  $e = 0$ , then

$$R_+ \subset \bigcup_{P \in \text{Ass } M} P,$$

so  $R_+$  is itself an associated prime. It is immediate that  $\Gamma(M) = H^0(M) \neq 0$  as desired.

For the inductive step, assume that (1) is true for all  $R$ -modules  $N$  with  $\text{depth } N < e$ . Let  $a \in R_+$  be a homogeneous NZD on  $M$  and let  $N = M/aM$ . Then  $\text{depth}_R N = e - 1$ , so by induction  $H^i(N) = 0$  for  $i < e - 1$  and  $H^{e-1}(N) \neq 0$ .

By general homological nonsense, the short exact sequence of  $R$ -modules

$$(1) \quad 0 \rightarrow M \xrightarrow{a} M \rightarrow N \rightarrow 0$$

induces a long exact sequence on cohomology

$$(2) \quad \dots \rightarrow H^{i-1}(M) \rightarrow H^{i-1}(N) \rightarrow H^i(M) \xrightarrow{a} H^i(M) \rightarrow \dots$$

If  $i < e$ , then  $H^{i-1}(N) = 0$ , so  $a$  is a NZD on  $H^i(M)$ . But  $H^i(M)$  is  $R_+$ -torsion and so has depth 0. It follows that  $H^i(M) = 0$ .

On the other hand, if  $i = e$  then the first three terms displayed in (2) are

$$0 \rightarrow H^{e-1}(N) \rightarrow H^e(M),$$

and  $H^e(M) \neq 0$  since  $H^{e-1}(N) \neq 0$ . □

The local cohomology functors can be computed using the **Čech complex**  $\check{C}^\bullet(x_1, \dots, x_n; M)$ , which is defined as

$$(3) \quad \check{C}^\bullet(x_1, \dots, x_n; M) := \bigotimes_{i=1}^n ((0 \rightarrow R \rightarrow R_{x_i} \rightarrow 0) \otimes M).$$

where  $R_+ = \sqrt{(x_1, \dots, x_n)}$  and  $R_{x_i} = R[x_i^{-1}]$ . The  $i$ th Čech module  $\check{C}^i(x_1, \dots, x_n; M)$  may be described explicitly as follows. For  $F \subset [n]$ , define

$$x_F = \prod_{i \in F} x_i$$

and let

$$R_F = R[x_F^{-1}].$$

Then

$$(4) \quad \check{C}_i^\bullet(x_1, \dots, x_n; M) = \bigoplus_{\substack{F \subset [n] \\ |F|=i}} M_F$$

where  $M_F = M \otimes R_F$  and the maps between adjacent terms in the Čech complex are given by the usual Koszul maps (just like simplicial cohomology.)

### 3. HOCHSTER'S THEOREM

Let  $\Delta$  be a simplicial complex on vertices  $x_1, \dots, x_n$ , and  $R = \mathbf{k}[\Delta] = \mathbf{k}[x_1, \dots, x_n]/I_\Delta$  its Stanley-Reisner ring. With respect to the obvious  $\mathbb{N}^n$ -grading, we have  $R_+ = (x_1, \dots, x_n)$ .

**Definition 7.** Let  $F \in \Delta$ . The **star** of  $F$  with respect to  $\Delta$  is

$$\text{st}_\Delta F := \{G \in \Delta \mid G \cup F \in \Delta\}$$

and the **link** of  $F$  with respect to  $\Delta$  is

$$\text{lk}_\Delta F := \{G \in \Delta \mid G \cup F \in \Delta, G \cap F = \emptyset\}.$$

We suppress the subscript when possible.

Note that both  $\text{st} F$  and  $\text{lk} F$  are simplicial complexes, and that  $\text{st} F = \langle F \rangle * \text{lk} F$ . For instance, if  $\Delta = \langle 123, 14, 24 \rangle$  and  $F = 12$ , then  $\text{lk} F = \langle 3 \rangle$  and  $\text{st} F = \langle 123 \rangle$ .

Let  $q_1, \dots, q_n$  be indeterminates. Denote by  $\text{Hilb}(M; q)$  the finely graded Hilbert series of  $M$ , i.e.,

$$\text{Hilb}(M; q) := \sum_{\alpha \in \mathbb{Z}^n} q^\alpha \dim_{\mathbf{k}} M_\alpha,$$

where  $q^\alpha = q_1^{\alpha_1} \dots q_n^{\alpha_n}$ . Also, let  $\check{H}_i(\Delta; \mathbf{k})$  denote the  $i$ th reduced simplicial homology of a simplicial complex  $\Delta$  with coefficients in  $\mathbf{k}$ .

For  $\alpha \in \mathbb{Z}^n$ , define

$$\begin{aligned} F(\alpha) &= \{x_i \mid \alpha_i < 0\}, \\ G(\alpha) &= \{x_i \mid \alpha_i > 0\}, \\ \text{supp}(\alpha) &= F(\alpha) \cup G(\alpha) = \{x_i \mid \alpha_i \neq 0\}. \end{aligned}$$

**Theorem 8** (Hochster). *We have*

$$\text{Hilb}(H^i(\mathbf{k}[\Delta]); q) = \sum_{F \in \Delta} \dim_{\mathbf{k}} \check{H}_{i-|F|-1}(\text{lk}_\Delta F; \mathbf{k}) \prod_{x_i \in F} \frac{q_i^{-1}}{1 - q_i^{-1}}.$$

*Proof.* We compute  $H^i(R)$  explicitly as the  $i$ th cohomology of the Čech complex  $\check{C}^\bullet = \check{C}^\bullet(x_1, \dots, x_n; M)$ . If  $F \notin \Delta$ , then the ring  $R_F$  is zero, because  $x_F = 0$  in  $R$ . On the other hand, if  $F \in \Delta$ , then the variables in  $F$  become units in  $R_F$ , and those not in  $\text{st}_\Delta F$  get killed (since they annihilate the unit  $x_F$ ). That is,

$$R_F = \mathbf{k}[\{x_i, x_i^{-1} : i \in F\} \cup \{x_j : x_j \in \text{lk} F\}] \otimes R.$$

Let  $\alpha \in \mathbb{Z}^n$ . We will compute the  $\alpha$ th graded piece  $\check{C}_\alpha^\bullet$  of the Čech complex. If  $\text{supp}(\alpha) \notin \Delta$ , then  $\check{C}_\alpha^\bullet = 0$ , because  $R_\alpha = 0$  and adjoining inverses doesn't change this. So suppose that  $\text{supp}(\alpha) \in \Delta$ . Let  $F = F(\alpha)$ ,  $j = |F|$ , and  $G = G(\alpha)$ . A priori, we have

$$(5) \quad \check{C}_\alpha^r = \left[ \bigoplus_{|F'|=r} R_{F'} \right]_\alpha = \bigoplus_{|F'|=r} [R_{F'}]_\alpha.$$

A whole bunch of these summands are zero. Specifically, for  $R_{F'}$  to be nonzero, we must have  $F' \in \Delta$  (as previously noted),  $F' \supset F$  (since the variables in  $F$  must be units in the  $\alpha$ th graded piece of the Čech complex), and  $F' \cup G \in \Delta$  (so that  $x^\alpha$  itself is nonzero). This is all equivalent to the condition that  $F'' = F' \setminus F$  belong to  $\text{lk}_{\text{st}_G F}$ , so we may write

$$(6) \quad \check{C}_\alpha^r = \left[ \bigoplus_{\substack{F'' \in \text{lk}_{\text{st}_G F} \\ |F''|=r-j}} R_{F \cup F''} \right]_\alpha.$$

The maps in  $\check{C}_\alpha^r$  correspond to the usual coboundary maps of the simplicial cochain complex of  $\text{lk}_{\text{st } G} F$ , shifted by  $j + 1$ . That is,

$$(7) \quad [H^i(R)]_\alpha = \check{H}^{i-j-1}(\text{lk}_{\text{st } G} F; \mathbf{k})$$

$$(8) \quad \cong \check{H}_{i-j-1}(\text{lk}_{\text{st } G} F; \mathbf{k})$$

since this is a finite-dimensional  $\mathbf{k}$ -vector space, hence isomorphic to its dual. (The isomorphism is not canonical, but we don't care because we're really only interested in its dimension.)

If  $G \neq \emptyset$ , then  $\text{lk}_{\text{st } G} F$  is a cone over  $G$ . In particular it is contractible, so  $\check{H}_\bullet(\text{lk}_{\text{st } G} F; \mathbf{k}) = 0$ . Therefore we only have nonzero terms when  $G = \emptyset$ , so  $\text{lk}_{\text{st } G} F = \text{lk}_\Delta F$  and the last equation becomes

$$(9) \quad [H^i(R)]_\alpha \cong \check{H}_{i-j-1}(\text{lk } F; \mathbf{k}).$$

Therefore

$$(10) \quad \text{Hilb}(H^i(\mathbf{k}[\Delta]); q) = \sum_{F \in \Delta} \sum_{\substack{\alpha: \\ \text{supp}(\alpha) = F(\alpha) = F}} \dim_{\mathbf{k}} \check{H}_{i-|F|-1}(\text{lk } F; \mathbf{k}) q^\alpha$$

$$(11) \quad = \sum_{F \in \Delta} \dim_{\mathbf{k}} \check{H}_{i-|F|-1}(\text{lk } F; \mathbf{k}) \sum_{\substack{\alpha: \\ \text{supp}(\alpha) = F(\alpha) = F}} q^\alpha$$

$$(12) \quad = \sum_{F \in \Delta} \dim_{\mathbf{k}} \check{H}_{i-|F|-1}(\text{lk } F; \mathbf{k}) \prod_{x_i \in F} \frac{q_i^{-1}}{1 - q_i^{-1}}$$

as desired. □

Here's an example (from Stanley) of computing a Čech complex. Let  $\Delta$  be the complex  $\langle 12, 13, 23, 4 \rangle =$

and  $R = \mathbf{k}[\Delta] = \mathbf{k}[x_1, x_2, x_3, x_4]/(x_1x_4, x_2x_4, x_3x_4, x_1x_2x_3)$ . Then the Čech complex is

$$0 \rightarrow \underbrace{R}_{\check{C}^0} \rightarrow \underbrace{R_1 \oplus R_2 \oplus R_2 \oplus R_3 \oplus R_4}_{\check{C}^1} \rightarrow \underbrace{R_{12} \oplus R_{13} \oplus R_{23}}_{\check{C}^2} \rightarrow 0,$$

where  $R_1 = R[x_1^{-1}]$ ,  $R_{12} = R[x_1^{-1}, x_2^{-1}]$ , etc.

- For  $\alpha = (0, 0, 0, 0)$ , so  $F(\alpha) = G(\alpha) = \emptyset$ , we have

$$\text{lk}_{\text{st } G} F = \text{lk}_\Delta \emptyset = \Delta,$$

$$\text{so } [H^i(R)]_\alpha = \check{H}_{i-1}(\Delta; \mathbf{k}).$$

- For  $\alpha = (-2, 3, 0, 0)$ , we have

$$F = \{x_1\}, \quad G = \{x_2\}, \quad \text{lk}_{\text{st } G} F = \langle x_2 \rangle \text{ (i.e., a point)}$$

$$\text{so } [H^i(R)]_\alpha = \check{H}_{i-2}(\text{point}) = 0.$$

#### 4. REISNER'S THEOREM

Let  $\Delta$  be a simplicial complex and  $R = -\mathbf{k}[\Delta]$ . Let  $d = \dim R = 1 + \dim \Delta$ . We will say that  $\Delta$  satisfies **Reisner's criterion** if for all  $F \in \Delta$ , and  $i < \dim(\text{lk } F)$ . we have

$$\check{H}_i(\text{lk } F; \mathbf{k}) = 0.$$

**Theorem 9.**  $\Delta$  is Cohen-Macaulay if and only if it satisfies Reisner's criterion.

**Remark:**  $\Delta$  is **Gorenstein** (a stronger condition than Cohen-Macaulayness) if in addition  $\tilde{H}_i(\text{lk } F; \mathbf{k}) \cong \mathbf{k}$  for  $i = \dim(\text{lk } F)$ .

*Proof.* First, we show that a Cohen-Macaulay complex is pure (i.e., all maximal faces have the same dimension). Indeed, if  $\Delta$  is Cohen-Macaulay of dimension  $d - 1$  and  $\dim F < d - 1$ , then  $\tilde{H}_{-1}(\text{lk } F) = 0$  by Hochster's theorem, so  $\text{lk } F \neq 0$  and  $F$  is not maximal. (This can also be shown without Hochster's theorem; see Bruns and Herzog, p. 210.)

Next, we show that a complex  $\Delta$  satisfying Reisner's criterion is pure. If  $\dim F = 0$  then there is nothing to show. Otherwise, we induct on dimension. Reisner's criterion gives  $\tilde{H}_0(\Delta) = \tilde{H}_0(\text{lk } \emptyset) = 0$ , so  $\Delta$  is connected. Moreover, for every vertex  $v$ , the subcomplex  $\text{lk}\{v\}$  of  $\Delta$  satisfies Reisner's criterion and has dimension less than that of  $\Delta$ , so it is pure by induction. Now, for any maximal face  $F$ , let  $v, w \in F$ ; we have

$$\dim \text{lk}\{v\} = |F - v| - 1 = |F - w| - 1 = \dim \text{lk}\{w\};$$

by connectedness all links of vertices must have the same dimension, and the same equation implies that  $\Delta$  is pure.

By these two observations together, we may assume that  $\Delta$  is pure, so  $|F| = d$  for all maximal faces and  $\dim(\text{lk } F) = d - |F| - 1$  for all faces. So Cohen-Macaulayness

$$\begin{aligned} F \text{ is Cohen-Macaulay} &\iff \mathbf{k}[\Delta] \text{ is Cohen-Macaulay} \\ &\iff \tilde{H}_{j-|F|-1}(\text{lk } F; \mathbf{k}) = 0 \text{ for } j < d, F \in \Delta \end{aligned}$$

which is exactly Reisner's criterion (set  $j = i + |F| + 1$ ). □

By the way, a pure connected simplicial complex  $\Delta$  certainly need not be Cohen-Macaulay (unless  $\dim \Delta \leq 1$ ). The "minimal" example is the complex  $\langle 123, 345 \rangle =$

which is not Cohen-Macaulay because  $\text{lk}(3) = \langle 12, 45 \rangle$  is disconnected, so has  $\tilde{H}_0 \neq 0$ . (Also, the  $h$ -vector of this complex can be computed as  $(1, 2, -1)$ . In a Cohen-Macaulay complex, every entry of the  $h$ -vector is nonnegative.)
