HOPF MONOIDS OF ORDERED SIMPLICIAL COMPLEXES

FEDERICO CASTILLO, JEREMY L. MARTIN, AND JOSÉ A. SAMPER

ABSTRACT. We study pure ordered simplicial complexes (i.e., simplicial complexes with a linear order on their ground sets) from the Hopf-theoretic point of view. We define a Hopf class to be a family of pure ordered simplicial complexes that give rise to a Hopf monoid under join and deletion/contraction. The prototypical Hopf class is the family of ordered matroids. The idea of a Hopf class allows us to give a systematic study of simplicial complexes related to matroids, including shifted complexes, broken-circuit complexes, and unbounded matroids (which arise from unbounded generalized permutohedra with 0/1 coordinates).

We compute the antipodes in two cases: facet-initial complexes (a much larger class than shifted complexes) and unbounded ordered matroids. In the latter case, we embed the Hopf monoid of ordered matroids into the Hopf monoid of ordered generalized permutohedra, enabling us to compute the antipode using the topological method of Aguiar and Ardila. The calculation is complicated by the appearance of certain auxiliary simplicial complexes that we call Scrope complexes, whose Euler characteristics control certain coefficients of the antipode. The resulting antipode formula is multiplicity-free and cancellation-free.

1. INTRODUCTION

1.1. Background: Matroids and combinatorial Hopf theory. The study of Hopf algebras and related structures in combinatorics dates back to the seminal work of Rota in the 1970s, notably his work with Joni [JR79] on coalgebras and bialgebras. The underlying idea is simple: joining and breaking of combinatorial objects — graphs, trees, posets, matroids, symmetric and quasisymmetric functions — are modeled algebraically by multiplication and comultiplication. Major works include Schmitt’s study of incidence Hopf algebras [Sch94] and Aguiar, Bergeron and Sottile’s theory of combinatorial Hopf algebras [ABS06], as well as the monograph by Grinberg and Reiner [GR14]. More recently, the subject has turned in a more category-theoretic direction with the introduction of Hopf monoids by Aguiar and Mahajan [AM10]; a survey of the subject accessible to combinatorialists appears in SS2–4 of [AA17]. Broadly speaking, a Hopf algebra is generated by unlabeled combinatorial objects while a Hopf monoid is generated by labeled objects, so the latter keeps track of more information.

A key to the structure of a Hopf algebra or a Hopf monoid is its antipode. Every group algebra is a Hopf algebra in which the antipode is (the linearization of) inversion in the group [GR14, Ex. 1.31], [AM10, p.88], so the antipode can be regarded as a generalization of group inversion. The antipode is defined via a certain commutative diagram and the general formula, known as the Takeuchi formula, typically exhibits massive cancellation, so one of the fundamental problems in studying a given Hopf algebra or monoid is to give a cancellation-free formula for its antipode.

Before going on, we give a brief working definition of a Hopf monoid; the full details are in §2.5 below. A vector species is a functor \( H \) from finite sets \( I \) with bijections to sets \( H[I] \) with bijections; one should think of \( H[I] \) as the space spanned by the set \( h[I] \) of combinatorial objects of a given type labeled by \( I \) (for example, graphs with vertices \( I \) or matroids on ground set \( I \)). A Hopf monoid in vector species is a vector species \( H \) equipped
with linear maps $\mu_{S,T} : H[S] \otimes H[T] \to H[I]$ (product) and $\Delta_{S,T} : H[I] \to H[S] \otimes H[T]$ (coproduct) for all decompositions $I = S \sqcup T$; the maps must satisfy certain compatibility conditions.

The Hopf algebra of matroids was introduced by Crapo and Schmitt [CS05a, CS05b, CS05c]. The corresponding Hopf monoid was described by Aguiar and Mahajan [AM10, §13.8.2] and has attracted recent interest; see, e.g., [San20, Sup20, AS20, Bas20]. There are many definitions of a matroid (see, e.g., [Oxl11, Section 1]), but for our purposes the most convenient definition is that a matroid is a simplicial complex $\Gamma$ on vertex set $I$ such that the induced subcomplex $\Gamma|S = \{\sigma \in \Gamma : \sigma \subseteq S\}$ is pure for every $S \subseteq I$ (i.e., every facet of $\Gamma|S$ has the same size). In fact the following condition, which we call link-invariance, is equivalent: for every $S \subseteq I$, all facets of $\Gamma|S$ have identical links. (Recall that the link of a face in a simplicial complex is defined as $\text{link}_{\Gamma}(\phi) = \{\sigma \in \Gamma : \sigma \cap \phi = \emptyset, \sigma \setminus \phi \in \Gamma\}$.) This characterization of matroid complexes appears to be new (Theorem 2.10).

Link-invariance is crucial to the definition of the Hopf monoid $\text{Mat}$ of matroids: product is given by direct sum and coproduct by restriction/contraction. Specifically, for matroids $\Gamma_1, \Gamma_2, \Gamma$ on ground sets $S, T, I$ one defines

$$
\mu_{S,T}(\Gamma_1, \Gamma_2) = \Gamma_1 \ast \Gamma_2 = \{\sigma_1 \cup \sigma_2 : \sigma_1 \in \Gamma_1, \sigma_2 \in \Gamma_2\},
$$

$$
\Delta_{S,T}(\Gamma) = \Gamma|S \otimes \Gamma|T
$$

where $\Gamma|S = \text{link}_{\Gamma}(\phi)$ for any facet $\phi \in \Gamma|S$. Since link-invariance characterizes matroid complexes, no larger subspecies of $\text{SC}$ can be made into a Hopf monoid in this way.\(^1\)

1.2. Ordered simplicial complexes. One of the goals of our work is to use combinatorial Hopf theory to study pure simplicial complexes that generalize or behave similarly to matroids, or that exhibit similar behavior. Two well-known examples of such classes include pure shifted complexes [Kal02, BK88] and broken-circuit complexes of matroids [Bry77]. However, as we have just seen, there are two major difficulties to defining a Hopf structure on any species containing $\text{Mat}$. Difficulty 1, as mentioned above, is that link-invariance characterizes matroids, meaning that $\text{Mat}$ cannot be extended within $\text{SC}$. Difficulty 2 is that even the class of pure complexes is not closed under restriction; indeed, the largest class of pure complexes closed under restriction is precisely the set of matroid complexes.

To resolve these difficulties, we introduce a linear order $w$ on the vertex set of $\Gamma$. On a technical level, we can now overcome Difficulty 1 by defining $\Gamma|S$ unambiguously as the link of the lexicographically minimal facet of $\Gamma|S$ with respect to $w$ (following the ideas of [Sam20]). Introducing an order on the ground set is actually quite natural in the context of matroids and related structures. Matroids are characterized by uniform behavior in many ways with respect to all possible ground set orderings, while both shifted complexes and broken-circuit complexes (as well as the special class of matroids known as positroids; see [Pos07]) are controlled strongly by linear orderings of their vertex sets. As discussed in, e.g., [HS20, Sam20], it would be convenient to extend matroids to a larger class of complexes to facilitate various inductive arguments. As one example, one would like to attack Stanley’s notorious conjecture on pure O-sequences [Sta96, Conjecture III.3.6] by induction on the number of bases. Removing a basis does not in general

\(^1\)Benedetti, Hallam and Machacek [BHM16] considered a different Hopf structure on simplicial complexes, motivated by an analogous Hopf structure for graphs, in which product is given by disjoint union rather than join. Note that the disjoint union of matroids is in general not a matroid.
preserve the property of being a matroid complex, but it may preserve membership in a larger class. Another motivation for extending matroids arises in the theory of combinatorial Laplacians of simplicial complexes. The Laplacians of matroid complexes [KRS99] and shifted complexes [DR02] are known to have integer eigenvalues and satisfy a common recurrence relation [Duv05], raising the question of determining the largest class of simplicial complexes satisfying the recurrence.

Thus we are now looking for Hopf monoids in species whose standard bases are tensors \( w \otimes \Gamma \), where \( w \) is a linear order on the vertex set of the simplicial complex \( \Gamma \). That is, these species are subspaces of a Hadamard product of linear orders with \( SC \), with product and coproduct of simplicial complexes defined as just explained. There are two basic Hopf monoid structures on the species of linear orders, called \( L \) and \( L^* \) in [AA17, Examples 8.16 and 8.24]. The product in \( L \) is given by concatenation, while in \( L^* \) it is shuffle product.

The shuffle product is much better for our purposes, for several reasons. First and most importantly, the coproduct \( \Delta_{S,T} \) in \( L^* \) is nonzero only on linear orders \( w \) in which every element of \( S \) precedes every element of \( T \). This resolves Difficulty 2: rather than requiring that \( \Gamma \) be a matroid, we need only require that it be prefix-pure, that is, that every subcomplex induced by an initial segment of \( w \) is pure. (This is in practice a mild restriction; many classes of complexes of interest, including broken-circuit complexes and pure shifted complexes, are prefix-pure.) Second, shuffle product (but not concatenation) is commutative, meaning that the inherent commutativity of join is preserved in the Hadamard product. Third, using \( L^* \) rather than \( L \) turns out to be a more natural choice from the geometric viewpoint that we will describe soon.\(^2\)

Accordingly, we define a **Hopf class** as a class of ordered complexes that is closed under initial restriction, initial contraction, and ordered join. All the Hopf classes we will consider in this paper consist of prefix-pure complexes. Our main results about Hopf classes are as follows.

**Theorem A.** (Proposition 3.4 + Theorem 3.16) Every Hopf class \( H \) gives rise to a vector species \( H \subseteq L^* \times SC \) with the structure of a commutative Hopf monoid under the operations (1.1). Moreover, the Hopf class \( PRE \) of prefix-pure ordered complexes is the largest Hopf class all of whose members are pure complexes, so that the Hopf monoid \( Pre \) can be regarded as the universal Hopf monoid of pure ordered complexes.

**Theorem B.** (Section 3.2) The following collections (among others) are Hopf classes of prefix-pure ordered complexes.

1. Ordered matroids;
2. Strongly lexicographically shellable complexes, i.e., those for which every ordering on the ground set induces a shelling order on every restriction to an initial segment;\(^3\)
3. Broken-circuit complexes and their contractions;
4. Pure shifted simplicial complexes and their joins;
5. Color-shifted complexes in the sense of Babson and Novik [BN06];

\(^2\)On the other hand, positroids are closed under contractions and restrictions [ARW16, Prop. 3.5], but only under join if the orders are concatenated rather than shuffled.

\(^3\)This definition of lex-shellability is not to be confused with CL- or EL-shellability of the order complex of a poset as in, e.g., [Bjö80, BW82].
(6) Any complex in a quasi-matroidal class in the sense of [Sam20];
(7) Gale truncations of ordered matroids.

The known inclusions between these Hopf classes are shown in Figure 2.

The condition of prefix-purity actually appears (without a name) in the work of Brylawski [Bry77, p. 430] on broken-circuit complexes. There it is observed that matroids are strictly contained in the class of (reduced) broken-circuit complexes, which in turn are strictly contained in prefix-pure complexes.

In the course of this work, we have checked computationally that there exists simplicial complex (Lockeberg’s simplicial 3-sphere) that is shellable but not lexicographically shellable under any order (Remark 3.6). We believe this observation to be new.

1.3. Polyhedra. Having developed a purely algebraic and combinatorial theory of Hopf monoids of ordered simplicial complexes extending matroids, we now move to geometry. Every matroid \( M \) has an associated base polytope \( p_M \) defined as the convex hull of the characteristic vectors of its bases (and thus contains all the data of \( M \)). A far-reaching result of Gelfand, Goresky, MacPherson and Serganova [GGMS87, Thm. 4.1] states that a polyhedron \( p \subset \mathbb{R}^E \) is a matroid base polytope for some matroid on \( E \) if and only if \( p \) satisfies the following three conditions:

1. \( p \) is bounded;
2. \( p \) is an 0/1-polyhedron, that is, the coordinates of all vertices consist entirely of 0/1 vectors;
3. Every edge of \( p \) is parallel to some \( e_i - e_j \), where \( \{e_i\}_{i \in E} \) is the standard basis of \( \mathbb{R}^E \). Equivalently, the normal fan of \( p \) is a coarsening of the fan defined by the braid arrangement.

Conditions (M1) and (M3) define the class of generalized permutohedra, an important family of polytopes introduced under that name by Postnikov [Pos09] and equivalent to the polymatroids studied by Edmonds [Edm70]. Generalized permutohedra form a Hopf monoid \( \text{GP} \) that was studied intensively by Aguiar and Ardila [AA17]; in particular, the antipode of a generalized permutohedron \( p \) has an elegant formula [AA17, Thm. 7.1] in terms of the faces of \( p \). The Aguiar-Ardila formula is both cancellation-free (all summands are distinct) and multiplicity-free (all coefficients are \( \pm 1 \)). This theory carries over with little change to the family of extended generalized permutohedra, or possibly-unbounded polyhedra satisfying condition (M3). Moreover, the map \( M \to p_M \) identifies \( \text{Mat} \) with a Hopf submonoid of \( \text{GP} \). Meanwhile, every polyhedron \( p \) that satisfies (M2) and whose vertices have fixed coordinate sum gives rise to a pure simplicial complex \( \Upsilon(p) \), its indicator complex, whose facets are the supports of vertices of \( p \).

Accordingly, we next study Hopf monoid structures on species of more general ordered polyhedra than matroid base polytopes. (Here “ordered polyhedron” means “polyhedron whose ambient space is equipped with a linear order on its coordinates.”) We do not wish to drop (M3) which is fundamental to the structure of matroid polytopes. In fact, \( \text{GP} \) cannot be extended to any larger Hopf monoid of polyhedra with the same product and coproduct [AA17, Theorem 6.1], so we really are restricted to subspecies of \( \text{L}^* \times \text{GP} \); that is, whose basis elements are tensors \( w \otimes p \), where \( p \) is an (extended) generalized permutohedron in \( \mathbb{R}^I \) and \( w \) is a linear order on \( I \). On the other hand, it is
possible to drop one or both of conditions (M1) and (M2) to get interesting Hopf monoids of ordered polyhedra that generalize matroid polytopes.

**Theorem C. (Theorem 5.2 + Theorem 4.5)** The following relaxations of the conditions (M1) and (M2), while retaining (M2), produce Hopf monoids:

1. Retaining (M2) but dropping (M1) yields the species \( \text{OIGP}_+ \subseteq \text{L}^* \times \text{GP}_+ \), of ordered 0/1 extended generalized permutohedra. The map sending a polyhedron to its indicator complex gives rise to a Hopf morphism \( \tilde{\Upsilon} : \text{OIGP}_+ \to \text{Pre} \). The image is a Hopf monoid \( \text{OMat}_+ \) that arises from a Hopf class \( \text{OMAT}_+ \) of complexes that we call unbounded matroids.

2. Retaining (M1) but dropping (M2) yields the Hopf monoid \( \text{OGP} \) of ordered generalized permutohedra, which is just the Hadamard product \( \text{L}^* \times \text{GP} \).

3. Dropping both (M1) and (M2) yields the Hopf monoid \( \text{OGP}_+ \) spanned by pairs \( w \otimes p \) such that \( p \) is bounded in the direction defined by \( w \).

Two different 0/1 polyhedra can have the same indicator complex (Example 2.1). This implies that the map \( \tilde{\Upsilon} : \text{OIGP}_+ \to \text{Pre} \) mentioned above has a nontrivial kernel, which remains mysterious.

1.4. **Antipodes.** Having constructed a large family of Hopf monoids, we now wish to compute their antipodes; that is, to specialize the general Takeuchi formula to a cancellation-and multiplicity-free expression, if possible. We focus our attention on the special cases of shifted complexes and ordered generalized permutohedra.

In Section 6, we first focus on the class of ordered simplicial complexes that are facet-initial, i.e., whose lex-minimal facet is an initial segment of the order. This condition is much milder than being shifted, and in fact is enough to expand the Takeuchi formula and track most or all of the cancellation. The results may be summarized as follows:

**Theorem D. (Theorem 6.3 + Section 6.3)**

1. Equation (6.5) gives a simple (but not entirely cancellation-free) formula for the antipode of a facet-initial ordered complex.

2. For a shifted complex without loops or coloops, the formula (6.5) is cancellation-free.

3. Equation (6.11) gives a cancellation-free (but more complicated) antipode formula for facet-initial complexes. In particular, every coefficient in the antipode of a facet-initial complex is \( \pm 1 \).

4. For a shifted complex \( \Gamma \), equation (6.13) gives a slightly less complicated cancellation-free formula for the antipode. Moreover, each term in this formula can be interpreted geometrically as a face of a matroid polytope, for any matroid containing \( \Gamma \) as a subcomplex.

In Section 7, we compute the antipode in the Hopf monoid \( \text{OGP}_+ \) of ordered extended generalized permutohedra, and thus for its Hopf submonoid \( \text{OMat}_+ \) of ordered matroids. Our argument is inspired by the topological approach of Aguiar and Ardila: expand the Takeuchi formula in the standard basis for \( \text{OGP}_+ \), interpret each coefficient as the Euler characteristic of a simplicial complex obtained by intersecting some faces of the braid arrangement with the unit sphere, then use geometric arguments (e.g., convexity) to observe that these complexes are topological balls or spheres. However, the interaction between \( \text{L}^* \) and \( \text{GP}_+ \) produces considerable unforeseen complications. In particular, some of the terms in the antipode are governed by the Euler characteristics of certain auxiliary
simplicial complexes that we call Scrope complexes, generated by complements of intervals (see Section 7.1). A simple inductive argument (Proposition 7.2) shows that every Scrope complex is a homotopy ball or sphere, hence has Euler characteristic 1, 0, or $-1$; however, it is not clear how to “see” the topological type of a Scrope complex from its list of generators. Nevertheless, these complexes enable us to track all the cancellation in the Takeuchi formula.

**Theorem E.** (Theorem 7.15) There is a multiplicity-free and cancellation-free formula for the antipode of the Hopf monoid $OGP_+$.  

In light of Theorems D and E, we make the following conjecture.

**Conjecture F.** (Conjecture 6.1) The antipode for the Hopf monoid of the universal Hopf class $PRE$ is multiplicity-free.

The organization of the paper is as follows.

Section 2 reviews background material on simplicial complexes, matroids, generalized permutohedra and Hopf monoids. A reader familiar with the literature (particularly [AM10] and [AA17]) may wish to skip this section and refer to it as needed.

Section 3 defines the main objects of study: Hopf classes of ordered complexes. We give numerous examples and show how Hopf classes give rise to Hopf monoids.

Section 4 defines the Hopf monoids $OGP$ and $OGP_+$ of ordered (extended) generalized permutohedra, which extend $OMat$ and enable us to study it geometrically on the level of ordered matroid polytopes.

Section 5 describes the new class of unbounded matroids, defined as ordered simplicial complexes obtained from 0/1-generalized permutohedra that are not necessarily bounded.

Sections 6 and 7 contain the antipode formulas for facet-initial complexes and ordered generalized permutohedra, respectively.

Section 8 studies antipodes of special classes of generalized permutohedra for which the Scrope complexes can be understood explicitly. These polyhedra include hypersimplices (Proposition 8.4) and certain graphical zonotopes (Proposition 8.5); notably, in both of these cases, the Scrope complexes arise from certain spider preposets.

Section 9 concludes with several open questions.

## 2. BACKGROUND AND NOTATION

We begin by setting up definitions and notation for the objects we will need, including preposets, polytopes, generalized permutohedra, and Hopf monoids. Our presentation owes a great deal to [AA17] and [PRW08], although our notation and terminology differs from theirs in some cases. Generalized permutohedra were introduced by Postnikov [Pos09], and the connection to preposet combinatorics was developed in [PRW08]. For general references on polytopes and polyhedra, see [Grü03] and [Zie95]; for hyperplane arrangements, see [Sta07]. Hopf monoids are treated comprehensively in [AM10]; a more compact “user’s guide” appears in [AA17, §2].

Throughout, we will adhere to the notational conventions in the following table.
Example 2.1. Different 0/1-polyhedra may have identical indicator complexes. As the p
Note that dim(Γ) = 0, with reduced Euler characteristic 0, and the trivial complex Γ = {∅}, with reduced Euler characteristic −1.

For any non-void pure simplicial complex Γ on I of dimension d, we define the indicator polytope pΓ ⊂ R^I to be the convex hull of the indicator vectors of the facets of Γ. (This is the same construction that produces a base polytope from a matroid complex.) Note that dim(pΓ) ≤ |I| − 1, since the assumption that Γ is pure implies that pΓ lies in the affine hyperplane \{x ∈ R^I : \sum_i x_i = d + 1\}. Conversely, for any 0/1-polyhedron p ⊂ \{x ∈ R^I : \sum_i x_i = r\} ⊂ R^I, its indicator complex Υ(p) is defined as the pure simplicial complex generated by the supports of the vertices of p.

Example 2.1. Different 0/1-polyhedra may have identical indicator complexes. As the simplest example, consider the point p = (1, 1) ∈ R^2 and the ray q emanating from p in direction e_1 − e_2; both are 0/1-polyhedra, and Υ(p) = Υ(q) is a two-vertex simplex.

In general Υ(pΓ) = Γ for all simplicial complexes Γ, but p_{Υ(p)} = p if and only if p is a polytope.

If Γ_1, Γ_2 are simplicial complexes on vertex sets I_1, I_2 then the join Γ_1 * Γ_2 is the complex on I_1 △ I_2 defined by

Γ_1 * Γ_2 = {γ_1 ∪ γ_2 : γ_1 ∈ Γ_1, γ_2 ∈ Γ_2}.

(Here and subsequently I_1 △ I_2 means the set-theoretic disjoint union, or equivalently the coproduct in the category of sets.) At the level of polytopes we have

p_{Γ_1} × p_{Γ_2} = p_{Γ_1 * Γ_2}.  

Let S ⊆ I. The restriction Γ|S is the complex with vertex set S and faces \{S ∩ γ : γ ∈ Γ\}. (This complex may also be referred to as the deletion of I \ S, or the subcomplex induced by S.) The link of γ ∈ Γ is link_{Γ}(γ) = {β ∈ Γ : γ ∩ β = S, γ ∪ β ∈ Γ}; this is a simplicial complex on I \ S.

The symbol < always denotes the natural order on R; other partial orderings are denoted by symbols such as < and ≪. The symbol ▶ denotes the end of an example.

2.1. Simplicial complexes. For a general reference on simplicial complexes, see, e.g., [Sta96, §0.3] or [KN16]. A simplicial complex Γ on a finite set I is a (possibly empty) subset of 2^I closed under inclusion. The elements of I are vertices, the elements of Γ are faces and the maximal (under inclusion) faces are facets. A collection of faces γ_1, . . . , γ_r ⊆ I generates the complex ⟨γ_1, . . . , γ_r⟩, namely the union of their power sets. The dimension of a face γ ∈ Γ is dim γ = |γ| − 1; the dimension of Γ is the maximum dimension of a face; and Γ is pure if all facets have the same dimension. The reduced Euler characteristic of Γ is χ(Γ) = \sum_{γ∈Γ}(-1)^{dim γ}. This coincides with the reduced Euler characteristic of the standard topological realization |Γ|. It is necessary to distinguish between the void complex Γ = {}, with reduced Euler characteristic 0, and the trivial complex Γ = {∅}, with reduced Euler characteristic −1.

For any non-void pure simplicial complex Γ on I of dimension d, we define the indicator polytope pΓ ⊂ R^I to be the convex hull of the indicator vectors of the facets of Γ. (This is the same construction that produces a base polytope from a matroid complex.) Note that dim(pΓ) ≤ |I| − 1, since the assumption that Γ is pure implies that pΓ lies in the affine hyperplane \{x ∈ R^I : \sum_i x_i = d + 1\}. Conversely, for any 0/1-polyhedron p ⊂ \{x ∈ R^I : \sum_i x_i = r\} ⊂ R^I, its indicator complex Υ(p) is defined as the pure simplicial complex generated by the supports of the vertices of p.

Example 2.1. Different 0/1-polyhedra may have identical indicator complexes. As the simplest example, consider the point p = (1, 1) ∈ R^2 and the ray q emanating from p in direction e_1 − e_2; both are 0/1-polyhedra, and Υ(p) = Υ(q) is a two-vertex simplex.

In general Υ(pΓ) = Γ for all simplicial complexes Γ, but p_{Υ(p)} = p if and only if p is a polytope.

If Γ_1, Γ_2 are simplicial complexes on vertex sets I_1, I_2 then the join Γ_1 * Γ_2 is the complex on I_1 △ I_2 defined by

Γ_1 * Γ_2 = {γ_1 ∪ γ_2 : γ_1 ∈ Γ_1, γ_2 ∈ Γ_2}.

(Here and subsequently I_1 △ I_2 means the set-theoretic disjoint union, or equivalently the coproduct in the category of sets.) At the level of polytopes we have

p_{Γ_1} × p_{Γ_2} = p_{Γ_1 * Γ_2}.  

Let S ⊆ I. The restriction Γ|S is the complex with vertex set S and faces \{S ∩ γ : γ ∈ Γ\}. (This complex may also be referred to as the deletion of I \ S, or the subcomplex induced by S.) The link of γ ∈ Γ is link_{Γ}(γ) = {β ∈ Γ : γ ∩ β = S, γ ∪ β ∈ Γ}; this is a simplicial complex on I \ S.

The symbol < always denotes the natural order on R; other partial orderings are denoted by symbols such as < and ≪. The symbol ▶ denotes the end of an example.

2.1. Simplicial complexes. For a general reference on simplicial complexes, see, e.g., [Sta96, §0.3] or [KN16]. A simplicial complex Γ on a finite set I is a (possibly empty) subset of 2^I closed under inclusion. The elements of I are vertices, the elements of Γ are faces and the maximal (under inclusion) faces are facets. A collection of faces γ_1, . . . , γ_r ⊆ I generates the complex ⟨γ_1, . . . , γ_r⟩, namely the union of their power sets. The dimension of a face γ ∈ Γ is dim γ = |γ| − 1; the dimension of Γ is the maximum dimension of a face; and Γ is pure if all facets have the same dimension. The reduced Euler characteristic of Γ is χ(Γ) = \sum_{γ∈Γ}(-1)^{dim γ}. This coincides with the reduced Euler characteristic of the standard topological realization |Γ|. It is necessary to distinguish between the void complex Γ = {}, with reduced Euler characteristic 0, and the trivial complex Γ = {∅}, with reduced Euler characteristic −1.

For any non-void pure simplicial complex Γ on I of dimension d, we define the indicator polytope pΓ ⊂ R^I to be the convex hull of the indicator vectors of the facets of Γ. (This is the same construction that produces a base polytope from a matroid complex.) Note that dim(pΓ) ≤ |I| − 1, since the assumption that Γ is pure implies that pΓ lies in the affine hyperplane \{x ∈ R^I : \sum_i x_i = d + 1\}. Conversely, for any 0/1-polyhedron p ⊂ \{x ∈ R^I : \sum_i x_i = r\} ⊂ R^I, its indicator complex Υ(p) is defined as the pure simplicial complex generated by the supports of the vertices of p.

Example 2.1. Different 0/1-polyhedra may have identical indicator complexes. As the simplest example, consider the point p = (1, 1) ∈ R^2 and the ray q emanating from p in direction e_1 − e_2; both are 0/1-polyhedra, and Υ(p) = Υ(q) is a two-vertex simplex.

In general Υ(pΓ) = Γ for all simplicial complexes Γ, but p_{Υ(p)} = p if and only if p is a polytope.

If Γ_1, Γ_2 are simplicial complexes on vertex sets I_1, I_2 then the join Γ_1 * Γ_2 is the complex on I_1 △ I_2 defined by

Γ_1 * Γ_2 = {γ_1 ∪ γ_2 : γ_1 ∈ Γ_1, γ_2 ∈ Γ_2}.

(Here and subsequently I_1 △ I_2 means the set-theoretic disjoint union, or equivalently the coproduct in the category of sets.) At the level of polytopes we have

p_{Γ_1} × p_{Γ_2} = p_{Γ_1 * Γ_2}.  

Let S ⊆ I. The restriction Γ|S is the complex with vertex set S and faces \{S ∩ γ : γ ∈ Γ\}. (This complex may also be referred to as the deletion of I \ S, or the subcomplex induced by S.) The link of γ ∈ Γ is link_{Γ}(γ) = {β ∈ Γ : γ ∩ β = S, γ ∪ β ∈ Γ}; this is a simplicial complex on I \ S.
2.2. Matroids. A pure simplicial complex $\Gamma$ on $I$ is a matroid independence complex, or simply a matroid, if any of the following equivalent conditions hold (see [Sta96, §III.3]):

1. $\Gamma|_S$ is pure for every $S \subseteq I$.
2. $\Gamma|_S$ is shellable for every $S \subseteq I$. (See §3.2 for more on shellability.)
3. If $\gamma, \beta \in \Gamma$ and $|\gamma| > |\beta|$, then there exists $x \in \gamma \setminus \beta$ such that $\beta \cup \{x\} \in \Gamma$.
4. If $\varphi, \varphi'$ are facets and $x \in \varphi \setminus \varphi'$, then there exists $x' \in \varphi' \setminus \varphi$ such that $\varphi \setminus \{x\} \cup \{x'\}$ is a facet.
5. If $\varphi, \varphi'$ are facets and $x \in \varphi \setminus \varphi'$, then there exists $x' \in \varphi' \setminus \varphi$ such that $\varphi' \setminus \{x'\} \cup \{x\}$ is a facet.

In standard matroid theory terminology, $I$ is usually called the ground set of the matroid, faces of $\Gamma$ are called independent sets, and facets are called bases. The direct sum $M_1 \oplus M_2$ of two matroids $M_1, M_2$ is just their join as simplicial complexes (see (2.1)). The contraction $\Gamma/I$ can be defined as the link of any facet of $\Gamma|I$. Note that all restrictions and contractions of a matroid complex are themselves matroid complexes.

The indicator polytope of a matroid is called its base polytope. As mentioned in the introduction, [GGMS87, Thm. 4.1] states that $\Gamma$ is a matroid on $I$ if and only if every edge of $p_\Gamma$ is parallel to some $e_i - e_j$, where $\{e_i\}_{i \in I}$ is the standard basis of $\mathbb{R}^I$.

2.3. Set compositions, preposets, and the braid fan. Let $S$ be a finite set. A (set) composition $A = A_1 \cdot \cdots \cdot A_k$ of $S$ is an ordered list of nonempty, pairwise-disjoint subsets $A_i$ (blocks) whose union is $S$. The symbol $\operatorname{Comp}(S)$ denotes the sets of compositions of $S$; we abbreviate $\operatorname{Comp}(n) = \operatorname{Comp}([n])$ and write $A \models S$ to indicate that $A \in \operatorname{Comp}(S)$. In this notation, the vertical bars are called separators. We typically drop the commas and braces, e.g., writing $14|256|3$ rather than the more cumbersome $\{1, 4\}|\emptyset|\{2, 5, 6\}|\{3\}$. Note that the order of elements within each block is not significant. A set of compositions of $S$ is called an album.

The set $\operatorname{Comp}(n)$ is partially ordered by refinement: $A \supset B$ means that every block of $B$ is of the form $A_i \cup A_{i+1} \cup \cdots \cup A_{j-1} \cup A_j$. Equivalently, $B$ can be written by removing zero or more separators from $A$: e.g., $14|256|3 \supset 14|25|67|3 \supset 14|25|367$. The refinement ordering is ranked, with rank function $r(A) = |A| - 1$, and has a unique minimal element, namely the composition $A_0$ with one block. In fact, $\operatorname{Comp}(n)$ is a meet-semilattice, with meet $x \leq_{A \land B} y$ if $x \leq_A y$ or $x \leq_B y$. Every permutation $w \in \mathfrak{S}_n$ gives rise to a set composition $W$ with $n$ singleton blocks, namely

$$W = w(1) \mid w(2) \mid \cdots \mid w(n).$$ (2.3)

In particular, if $e$ is the identity permutation in $\mathfrak{S}_n$, then $E = 1|2|\cdots|n$ is the corresponding set composition.

A preposet $Q$ on $S$ is given by a relation $\leq_Q$ on $S$ that is reflexive ($x \leq_Q x$ for all $x \in S$) and transitive (if $x \leq_Q y$ and $y \leq_Q z$, then $x \leq_Q z$). We write $x < y$ if $x \leq y$ and $y \not< x$. The notation $x \equiv_Q y$ means that both $x \leq_Q y$ and $x \geq_Q y$; this is evidently an equivalence relation, whose equivalence classes are called the blocks of $Q$. An antichain in $Q$ is a subset $T \subseteq S$ such that $x \not< y$ for all $x, y \in T$. (Thus an antichain may contain more than one element of a a block.)

The preposet $Q$ gives rise to a poset $Q/\equiv_Q$ on its blocks. If this poset is a chain, i.e., either $x \leq_Q y$ or $x \geq_Q y$ for every $x, y \in S$, then $Q$ is a preorder. A linear extension of a preposet $Q$ is a preorder $R$ with the same blocks as $Q$ and such that $x \leq_Q y$ implies
for all \( x, y \). A preorder \( R \) contains the same information as the set composition \( A = A_1 | \cdots | A_k \), where the \( A_i \) are the blocks of \( R \), and \( x \leq_R y \) whenever \( x \in A_i, y \in A_j \), and \( i \leq j \).

The closure of a preposet \( Q \) is the album

\[
\mathcal{C}_Q = \{ A \in \text{Comp}(n) : i \leq_Q j \implies i \leq_A j \}.
\] (2.4)

The closure is an order ideal of \( \text{Comp}(n) \) under refinement, hence a sub-meet-semilattice. In the case that \( Q \) is a composition, the closure is a Boolean poset.

We now relate these definitions to the geometry of the braid arrangement, which consists of the \( \binom{n}{2} \) hyperplanes in \( \mathbb{R}^n \) defined by the equations \( x_i = x_j \) for \( 1 \leq i < j \leq n \). (For general background on hyperplane arrangements, see [Sta07].) The faces of the braid arrangement are relatively-open\(^4\) cones that partition \( \mathbb{R}^n \); the set of all faces is called the braid fan \( B_n \). Every composition \( A \models [n] \) determines a relatively open face \( \sigma_A \in B_n \) with \( \dim \sigma_A = |A| \), namely

\[
\sigma_A = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_i \leq x_j \text{ according as } i \leq_A j \},
\]

and this correspondence is a bijection.\(^5\) In fact \( A \succeq B \) if and only if \( \overline{\sigma_A} \supseteq \sigma_B \) (where the bar denotes topological closure), so the correspondence may be viewed as an isomorphism of posets. In particular, the maximal faces \( \sigma_w \in B_n \) correspond to permutations \( w \in \mathcal{S}_n \). For each preposet \( Q \), the album \( \mathcal{C}_Q \) corresponds to the closed subfan

\[
\mathcal{C}_Q = \{ \sigma_A \in B_n : A \in \mathcal{C}_Q \}
\]

whose maximal faces correspond to the linear extensions of \( Q \). The closed subfans of \( B_n \) that arise in this way are precisely those whose union is convex. In addition,

\[
\mathcal{C}_Q = \bigcup_A \sigma_A
\]

where \( A \) ranges over all linear extensions of \( Q \).

Let \( \Sigma^{n-2} \) be the intersection of the unit sphere in \( \mathbb{R}^n \) with the hyperplane \( x_1 + \cdots + x_n = 0 \). Thus \( \Sigma^{n-2} \) is an \( (n-2) \)-sphere, with a polytopal (in fact, simplicial) cell structure whose (open) faces are the intersections

\[
\overline{\sigma}_A = \Sigma^{n-2} \cap \sigma_A.
\]

The facets correspond to permutations in \( \mathcal{S}_n \), the vertices correspond to the separators of a set composition, and the empty face corresponds to the set composition \( A_0 \). Thus, for any closed subfan \( F \subseteq B_n \), we can interpret the quantity \( \sum_{\sigma \in F} (-1)^{\sigma} \) as the reduced Euler characteristic of the simplicial complex \( \hat{F} = \{ \hat{\sigma} : \sigma \in F \} \).

For example, let \( Q \) be the preposet on \( \{1, 2, \ldots, 8\} \) whose quotient poset \( Q/\equiv \) is shown at left below. The simplicial complex on the right is \( \hat{C}_Q = \Sigma^{n-2} \cap C_Q \); the labels of its faces comprise \( C_Q \). We have abbreviated the set compositions by, e.g., \( ac | bd = 167/23458 \).

\(^4\)A subset of \( \mathbb{R}^n \) is relatively open if it is an open subset of its affine span.

\(^5\)This is the reverse of the convention from that used in [AA17, §4.3], where earlier parts of the composition correspond to larger coefficients. Cf. Remark 4.3.
2.3.1. **Natural preposets and naturalization.** Suppose that the underlying set $S$ of a preposet $Q$ is equipped with a linear (total) order $w : S \to \lbrack \lbrack S \rbrack \rbrack$. A relation $x \leq_Q y$ is called $w$-unnatural if $w(x) > w(y)$. We say that $Q$ is $w$-natural if it has no $w$-unnatural strict relations (i.e., if $w(x) > w(y)$ and $x <_Q y$, then in fact $x \equiv_Q y$). Observe that a set composition is $w$-natural if and only if it coarsens $W$; in particular, its blocks are intervals with respect to $w$. For a preposet $Q$, there is a unique finest $w$-natural set composition $N_Q = N_{w,Q}$ such that for every $w$-unnatural relation $x \leq_Q y$, the interval $[y, x]_w = \{\in S : w(y) \leq w(z) \leq w(x)\}$ is contained in a block of $N_Q$. We say that $N_Q$ is the naturalization of $Q$ with respect to $w$.

**Example 2.2.** For each of the following preposets, the naturalization with respect to the natural order on the ground set is the composition with one block:

\[
\begin{array}{cc}
13 & 2 \\
14 & 2 \\
14 & 2 & 36
\end{array}
\]

**Proposition 2.3.** Let $Q$ be a preposet and let $w$ be a linear order on its ground set. Then $C_Q \cap C_W = C_{N_{w,Q}}$.

**Proof.** For simplicity, write $N = N_{w,Q}$, and assume w.l.o.g. that $w = e$ is the natural ordering on the ground set $[n]$. We have $N \in C_E$ by the construction of $N$. Suppose that $N \notin C_Q$, i.e., there exist $i, j$ such that $i \leq_Q j$ but $i \notin N j$. Then $j <_N i$ (since any two elements are comparable in the set composition $N$) and in particular $j < i$ (since $N$ is natural). But then the relation $i \leq Q j$ is unnatural, so by construction $i \equiv_N j$, a contradiction. It follows that $C_Q \cap C_E \supseteq C_N$.

Now we show the reverse inclusion. Since $C_N$ is an order ideal in $\text{Comp}(n)$, it suffices to show that every $A \in C_Q \cap C_E$ satisfies $A \vartriangleleft N$, for which it suffices to show that $x \equiv_A y$ whenever $x \leq_Q y$ and $x > y$. Indeed, $x \leq_Q y$ implies $x \leq_A y$ by the definition of $C_Q$, and $x > y$ implies $x \geq_A y$ by the definition of $C_E$. \hfill $\Box$

2.4. **Generalized permutohedra.** Let $p \subset \mathbb{R}^n$ be a polyhedron. For each $x \in \mathbb{R}^n$, let $\lambda_x$ be the linear functional on $\mathbb{R}^n$ given by $\lambda_x(y) = x \cdot y$, and let $p_x$ be the face of $p$ maximized by $\lambda_x$. The normal cone of a face $q \subset p$ is

$$N^o_p(q) = \{x \in \mathbb{R}^n : p_x = q\}.$$
This is a relatively open polyhedral cone of dimension \( n - \dim q \). The normal cones of faces comprise the normal fan \( \mathcal{N}_p \).

The standard permutohedron is the polytope in \( \mathbb{R}^n \) whose vertices are the \( n! \) permutations of the vector \((1, 2, \ldots, n)\). Its normal fan is precisely the braid fan \( B_n \), and its faces correspond bijectively to set compositions of \([n]\).

**Definition 2.4.** The polytope \( p \) is a generalized permutohedron (or GP) if any of the following equivalent conditions holds \([AA17, \text{Thm. 12.3}]\):

1. \( \mathcal{N}_p \) is a coarsening of the braid fan \( B_n \), that is, each normal cone is a union of braid faces.
2. For each \( x \in \mathbb{R}^n \), the face of \( p \) maximizing \( \lambda_x \) depends only on equalities and inequalities among the coordinates of \( x \).
3. Every edge of \( p \) is parallel to \( e_i - e_j \), where \( \{e_1, \ldots, e_n\} \) is the standard basis of \( \mathbb{R}^n \).

In light of condition (2), every set composition \( A \vDash n \) gives rise to a face \( p_A \subseteq p \) defined by

\[
p_A = \{ x \in p : \lambda(x) \geq \lambda(y) \ \forall \lambda \in \sigma_A, \ y \in p \}.
\]

If \( A \) is a maximal set composition (i.e., with \( n \) blocks), then the braid cone \( \sigma_A \) has full dimension, hence is contained in a full-dimensional cone of \( \mathcal{N}_p \), so \( p_A \) is a vertex of \( p \) (and all vertices arise in this way). Moreover, for each face \( q \subseteq p \), the album of compositions

\[
\{ A \vDash n : \sigma_A \subseteq \mathcal{N}_p^\circ(q) \} = \{ A \vDash n : p_A = q \}
\]

consists precisely of the set compositions coarsening some preposet \( Q \) on \([n]\), the normal preposet of \( q \). Often we will work simultaneously with a face \( q \) and its normal preposet \( Q \), which contain equivalent information. Notice that \( |Q| = n - \dim(q) \). The definition of a generalized permutohedron implies that normal cones of faces carry combinatorial structure. Accordingly, we define the following fans and their corresponding albums:

\[
\begin{align*}
\mathcal{C}_p^\circ &= \{ \sigma_A : \sigma_A \subseteq \mathcal{N}_p(q) \} = \{ \sigma_A : p_A = q \}, \\
\mathcal{C}_q &= \{ \sigma_A : \sigma_A \subseteq \mathcal{N}_p(q) \} = \{ \sigma_A : p_A \supseteq q \}, \\
\partial \mathcal{C}_q &= \mathcal{C}_q \setminus \mathcal{C}_q^\circ = \{ \sigma_A : p_A \supseteq q \},
\end{align*}
\]

In particular, \( \mathcal{C}_p = \mathcal{C}_p^\circ \) is the \((n - \dim p)\)-dimensional vector space of functions that are constant on \( p \), and \( \partial \mathcal{C}_p = \emptyset \). In the “full-dimensional” case \( \dim p = n - 1 \), the space \( \mathcal{C}_p \) is just the line \( \sigma_{\lambda_0} \).

The definition of \( \mathcal{C}_Q \) is consistent with \((2.4)\). The following lemma gives the geometry-combinatorics dictionary explicitly. For \( A \in \mathcal{C}_Q \), we say that \( A \) collapses a relation of \( Q \) if some block of \( A \) contains elements \( x, y \) for which \( x <_Q y \).

**Lemma 2.5.** Let \( Q \) be a preposet. Then

\[
\partial \mathcal{C}_Q = \{ A \in \mathcal{C}_Q : A \text{ collapses some relation of } Q \},
\]

\[
\mathcal{C}_Q^\circ = \{ A \in \mathcal{C}_Q : A \text{ collapses no relation of } Q \}.
\]

**Proof.** The two claims are equivalent by \((2.4)\), and the description of \( \partial \mathcal{C}_Q \) is equivalent to \([PRW08, \text{Prop. 3.5(2)}]\). \hfill \Box

**Example 2.6 (A cone).** Consider the polyhedron

\[
p = \{ x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4 : x_3 \leq 3, \quad x_4 \leq 4, \quad x_2 + x_4 \leq 6, \quad x_1 + x_2 + x_3 + x_4 = 10 \},
\]

\[
(2.7)
\]
which is a three-dimensional simplicial cone with vertex \( (1, 2, 3, 4) \) and rays in directions \( e_1 - e_3, e_1 - e_2, \) and \( e_2 - e_4. \) The normal cone of the vertex is the cone given by the inequalities \( x_1 \leq x_2 \leq x_4 \) and \( x_1 \leq x_3. \) This cone is subdivided by three braid cones as shown in Figure 1. For instance \( 1|2|4|3 \) is in the boundary while \( 1|2|3|4 \) is in the interior, which agrees with the fact that \( \{2, 4\} \) is a relation and \( \{3, 4\} \) is not.

![Figure 1](image.png)

**Figure 1.** The normal fan of the cone in Example 2.6.

Note that \( \partial \tilde{C}_q \) and \( \partial \tilde{B}_q \) are (closed) simplicial subcomplexes of \( \Sigma^{n-2} \), homeomorphic to \( \mathbb{R}^{n-\dim q-2} \) and \( S^{n-\dim q-3} \) respectively.

**Remark 2.7.** For every proper face \( q \subset p \), the origin is a vertex of \( C_q \), hence of \( \partial C_q \). Therefore, \( A_0 \in \tilde{C}_q \) if and only if \( q = p \). More generally, \( \tilde{C}_p \) is the space of linear functionals that are constant on \( p \); this is a vector space of dimension \( n - \dim p \). Also, if \( q_1, q_2 \) are faces of \( p \), then \( \overline{q_1} \subseteq \overline{q_2} \) if and only if \( C_{q_1} \supseteq C_{q_2} \).

The Cartesian product of two generalized permutohedra is also a generalized permutohedron: each edge of the product is the product of an edge of one factor and a vertex of the other, so condition (3) of Definition 2.4 is preserved by products. Moreover, for each generalized permutohedron \( p \subset \mathbb{R}^n \) and each decomposition \( I \sqcup J = [n] \), there exist GPs \( p|I \in \mathbb{R}^I \) and \( p/I \in \mathbb{R}^J \) such that:

\[
\sigma_{J|I} = p|I \times p/I
\]

[AA17, Prop. 5.2], where \( p_{J|I} \) is interpreted as in (2.5). Note that the cone \( \sigma_{J|I} \) consists of all linear functionals taking one value \( a \) on \( J \) and another value \( b > a \) on \( I \).

An extended generalized permutohedron (EGP) [AA17, Defn. 4.2] is a polyhedron whose normal fan coarsens some convex subfan of the braid fan \( B_n \subset \mathbb{R}^I = \mathbb{R}^n \). Equivalently, it is a polyhedron (not necessarily bounded) such that the affine span of every face is a translate of a subspace spanned by vectors of the form \( e_i - e_j \) [AA17, Thm. 12.5 and Remark 12.6]. Many of the above statements about generalized permutohedra can be carried over to this more general setting mutatis mutandis. For example, EGPs are preserved by products, and the face of \( p \) corresponding to a set composition (i.e., maximized by the linear functionals in some face of \( B \)) is an EGP whenever it is well-defined (i.e., whenever any, hence all, such functionals are bounded from above on \( p \)).
2.5. **Species and Hopf monoids.** We briefly introduce notation and terminology for Hopf monoids. As far as possible, we follow the “user’s guide” of Ardila and Aguiar [AA17, §2]. For a comprehensive treatment of Hopf monoids, see [AM10].

A set species is a rule $p$ that associates with each finite set $X$ a set $p[X]$, and with each bijection $\phi : X \to Y$ a bijection $p[\phi] : p[X] \to p[Y]$, with the properties that $p[\text{Id}_X] = \text{Id}_{p[X]}$ and $p[\phi \circ \psi] = p[\phi] \circ p[\psi]$. Likewise, a vector species $P$ over a field $\mathbb{k}$ associates with each finite set $X$ a $\mathbb{k}$-vector space $P[X]$, and with each bijection $\phi : X \to Y$ a vector space isomorphism $P[\phi] : P[X] \to P[Y]$, with the same properties (replacing $P$ with $P$). Every set species $p$ gives rise to a vector species $P$, where $P[X] = \mathbb{k}^{p[X]}$ is the vector space with basis $p[X]$. A vector species arising in this way is called linearized, and the elements in the image of the corresponding set species are its canonical basis. (On the other hand, even vector species that are not linearized often come equipped with canonical bases.) Equivalently, a set or vector species is a functor from the category of finite sets with bijections to sets with functions, or vector spaces with linear transformations.

A set species $p$ is connected if $|p(\emptyset)| = 1$; a vector species $P$ is connected if $\dim P(\emptyset) = 1$. In this case the linear map $u : \mathbb{k} \to P(\emptyset)$ sending $1_\mathbb{k}$ to the canonical basis element of $p(\emptyset)$ is the unit of $p$, while the counit is the linear map $\epsilon$ that sends the basis element of $p(\emptyset)$ to $1_\mathbb{k}$ and all other basis elements to 0. For example, let $\text{sc}[I]$ be the set of all nonvoid simplicial complexes on vertex set $I$. Then $\text{sc}$ is a connected set species whose unit is the trivial complex and whose linearization is a connected vector species $\text{SC}$.

In general, we regard an element of $P[X]$ as a formal sum of combinatorial structures of a common kind, each labeled by the elements of $X$. Thus a vector species $P$ is linearized if $P = L \circ p$, where $p$ is a set species and $L$ is the functor from sets to vector spaces sending $X$ to $\mathbb{k}^X$. A morphism of species $\Psi : P \to P'$ is a collection of maps $\Psi[I] : P[I] \to P'[I]$ such that $P'[\phi] \circ \Psi[I] = \Psi[J] \circ P[\phi]$ for every bijection $\phi : I \to J$. (That is, it is a natural transformation $P \to P'$.)

A connected Hopf monoid in set species $h = (h, \mu, \Delta)$ is a connected set species $h$ together with a collection $\mu$ of maps $\mu_{I,J} : h[I] \otimes h[J] \to h[I \sqcup J]$ (products) and a collection $\Delta$ of maps $\Delta_{I,J} : h[I \sqcup J] \to h[I] \otimes h[J]$ (coproducts), satisfying several compatibility conditions [AA17, §2] that we do not reproduce in their entirety. Of particular importance are associativity of the product, coassociativity of the coproduct, and compatibility between the two, which say respectively that the following diagrams commute:

\[
\begin{array}{ccc}
h[I] \times h[J] \times h[K] & \xrightarrow{\mu_{I,J \times Id_K}} & h[I] \times h[J \sqcup K] \\
\downarrow \text{Id}_I \times \mu_{J,K} & & \downarrow \text{Id}_I \times \mu_{J,K} \\
\text{h}[I \sqcup J] \times h[K] & \xrightarrow{\mu_{I \sqcup J, K}} & h[I \sqcup J \sqcup K]
\end{array}
\]  

(associativity), \hspace{1cm} (2.9)

\[
\begin{array}{ccc}
h[I] \times h[J] \times h[K] & \xleftarrow{\Delta_{I,J \times Id_K}} & h[I] \times h[J \sqcup K] \\
\downarrow \text{Id}_I \times \Delta_{J,K} & & \downarrow \Delta_{I,J \sqcup K} \\
\text{h}[I \sqcup J] \times h[K] & \xleftarrow{\Delta_{I \sqcup J, K}} & h[I \sqcup J \sqcup K]
\end{array}
\]  

(coassociativity), \hspace{1cm} (2.10)
\[ h[I \sqcup J] \times h[K \sqcup L] \xrightarrow{\Delta_{I,J} \times \Delta_{K,L}} h[I] \times h[J] \times h[K] \times h[L] \]
\[ \xrightarrow{\mu_{I,J,K,L}} h[I \sqcup J \sqcup K \sqcup L] \xrightarrow{\Delta_{I \sqcup K,J \sqcup L}} h[I \sqcup K] \times h[J \sqcup L] \]

(2.11) (compatibility),

where \( \tau \) interchanges the second and third tensor factors.

A connected Hopf monoid in vector species (for short, a vector Hopf monoid) \( H = (H, \mu, u, \Delta, \epsilon) \) is a vector species \( H \) satisfying \( H[\emptyset] = k \), together with a collection \( \mu \) of linear maps \( \mu_{I,J} : H[I] \otimes H[J] \to H[I \sqcup J] \) (products) and a collection \( \Delta \) of linear maps \( \Delta_{I,J} : H[I \sqcup J] \to H[I] \otimes H[J] \) (coproducts). Again, the product and coproduct must satisfy various compatibility conditions; associativity and coassociativity are given by replacing \( h \) with \( H \) and \( \hat{\times} \) with \( \otimes \) in the diagrams defining these properties for a set species.

Intuitively, the product merges two labeled structures into one; the coproduct breaks a structure into sub- and/or quotient structures. A Hopf monoid is called commutative if \( \mu_{I,J} \circ t = \mu_{J,I} \) for all \( I, J \), and cocommutative if \( t \circ \Delta_{I,J} = \Delta_{J,I} \circ t \) for all \( I, J \), where \( t \) is the “twist” map \( t(x, y) = (y, x) \) (for set species) or \( t(x \otimes y) = y \otimes x \) (for vector species). A morphism of vector Hopf monoids \( H \to H' \) (for short, a Hopf morphism) is a morphism of species that preserves products, coproducts, and the unit.

It is often convenient to use abbreviated notation for the product and coproduct:

\[ \mu_{I,J}(x, y) = x \cdot y, \quad \Delta_{I,J}(x) = x|I \otimes x/I. \]  

The latter notation can be used only when the coproduct is a pure tensor; fortunately, this is typically the case in our setting, where \( x|I \) and \( x/I \) are defined combinatorially.

A Hopf monoid \( H \) in vector species is linearized if (i) it is linearized as a vector species, i.e., \( H = L \circ h \) for some set species \( h \); and (ii) its product and coproduct maps are linearizations of those of \( h \). (See [AM10, §8.7.2].) In particular, one property of a linearized Hopf monoid is that \( \mu(x, y) \) and \( \Delta(x) \) are nonzero for all canonical basis elements \( x, y \).

The product and coproduct operations can be iterated. For \( A = A_1|A_2| \ldots |A_k \models I \) (allowing empty blocks), there are maps

\[ \mu_A = \mu_{A_1, \ldots, A_k} : \bigotimes_{i=1}^k H[A_i] \to H[I], \]
\[ \Delta_A = \Delta_{A_1, \ldots, A_k} : H[I] \to \bigotimes_{i=1}^k H[A_i]. \]

Associativity and coassociativity imply that these maps are uniquely defined.

**Definition 2.8.** The antipode of a vector Hopf monoid \( H \) is the morphism (in fact, isomorphism) \( s_H^H : H \to H \) given by the Takeuchi formula

\[ s_H^H[I] = \sum_{A \in \text{Comp}(I)} (-1)^{|A|} \mu_A \circ \Delta_A \]  

(2.13)
[AA17, Defn. 2.11], [AM10, Prop. 8.13]. The antipode can also be defined as the unique morphism satisfying $\mu \circ (\text{Id} \otimes s) \circ \Delta = \mu \circ (s \otimes \text{Id}) \circ \Delta = u \circ e$ [AM10, Defn. 1.15]. (Here and subsequently we often drop one or both of $I$ and $H$ from the notation if no confusion can arise.)

The antipode is a key part of the structure of a connected Hopf monoid in vector species. The Takeuchi formula typically involves considerable cancellation, so in studying a particular Hopf monoid one typically looks for a cancellation-free formula. If $H$ is commutative or cocommutative, then the antipode is an involution [AM10, p.245].

The Hadamard product [AM10, §8.13] of two Hopf monoids $(H, \mu, \Delta)$ and $(H', \mu', \Delta')$ is the Hopf monoid $H \times H'$ defined by

$$(H \times H')[I] = H[I] \otimes H'[I], \quad (\mu \times \mu')_{I,J} := \mu_{I,J} \otimes \mu'_{I',J'}, \quad (\Delta \times \Delta')_{I,J} := \Delta_{I,J} \otimes \Delta'_{I,J}.$$}

There is no known general formula for the antipode of a Hadamard product in terms of the antipodes of the factors (and results such as Theorem 7.15 demonstrate that the antipode in the product can be much more complicated than those in the factors).

2.6. Examples of Hopf monoids. There are Hopf monoid structures on the species of linear orders (with two different products), matroids, and generalized permutohedra. We describe here what we need about these Hopf monoids; more details are in [AA17] and [AM10].

$L$: Linear orders with concatenation product. For any finite set $I$, let $\ell[I]$ denote the set of linear orders on $I$, i.e., all bijections $w : [n] \to I$, where $n = |I|$. We represent $w$ by a bracketed list $[w(1), \ldots, w(n)]$ or (when no confusion can arise) a string $w(1) \cdots w(n)$. Thus $\ell$ is a set species, which can be made into a Hopf monoid as follows: the product $\mu_{I,J}^L : \ell[I] \otimes \ell[J] \to \ell[I \sqcup J]$ is concatenation, and the coproduct $\Delta_{I,J}^L$ maps $w$ to $w|_I \otimes w|_J$, where $w|_I$ and $w|_J$ are the orders induced by $w$ on $I, J$ respectively. For example, if $I = \{a, b, c\}$ and $J = \{d, e\}$, then

$$\mu_{I,J}^L(312, 45) = 31245, \quad \Delta_{I,J}^L(14325) = (132, 45),$$
$$\mu_{I,J}^L(45, 312) = 45312, \quad \Delta_{I,J}^L(14325) = (45, 132).$$

(In particular, $\ell$ is cocommutative but not commutative.) We then define $L$ to be the linearization of $\ell$. The antipode in $L$ is given [AM10, p.250] by $s^L(w) = (-1)^{|I|}w^\text{rev}$, where $(w(1), \ldots, w(n))^\text{rev} = (w(n), \ldots, w(1))$.

$L^*$: Linear orders with shuffle product. More important for our purposes is the dual monoid $L^*$. For the general theory of duality on Hopf monoids, see [AM10, §8.6]; here we give a self-contained description of $L^*$. As a vector species, $L^*[I]$ is again the $\mathbb{k}$-vector space spanned by all linear orders of $I$. To define the product and coproduct on $L^*$, we first need to introduce the notion of a shuffle.

Let $w^{(1)}, \ldots, w^{(q)}$ be linear orders on pairwise-disjoint sets $I_1, \ldots, I_q$. A shuffle of the $w^{(i)}$ is an ordering on $I = I_1 \cup \cdots \cup I_q$ that restricts to $w^{(i)}$ on each $I_i$. The set of all shuffles is denoted $\text{Shuffle}(w^{(1)}, \ldots, w^{(q)})$. For example, $\text{Shuffle}(12, 3) = \{123, 132, 312\}$ and $\text{Shuffle}(12, 34) = \{1234, 1324, 1342, 3124, 3142, 3412\}$. The shuffle operation is commutative and associative, and $|\text{Shuffle}(w^{(1)}, \ldots, w^{(q)})| = (|I_1|, \ldots, |I_q|)$. The product on $L^*$ is defined
using shuffles:
\[
\mu_{I,J}(w, u) = \sum_{v \in \text{Shuffle}(w, u)} v. \tag{2.14a}
\]

Second, let \( w = (w(1), \ldots, w(n)) \in \ell[I] \). An initial segment of \( w \) is a set of the form \( \text{ini}_k(w) = \{w(1), \ldots, w(k)\} \) for some \( k \in [0, n] \); the complement of an initial segment is a final segment. The set of all initial segments of \( w \) is denoted \( \text{Init}(w) \). With this in hand, the coproduct on \( L^* \) is defined by
\[
\Delta_{I,J}(w) = \begin{cases} w|I \otimes w|J & \text{if } I \in \text{Init}(w), \\ 0 & \text{otherwise}. \end{cases} \tag{2.14b}
\]

Thus \( \Delta_{I,J}(w) \) is nonzero if and only if all elements of \( I \) precede all elements of \( J \) in \( w \). For example, if \( I = \{1, 2, 3\} \) and \( J = \{4, 5\} \), then
\[
\Delta_{I,J}(31254) = 312 \otimes 54 \quad \text{but} \quad \Delta_{I,J}(13425) = 0.
\]

Note that \( L^* \) is commutative but not cocommutative (in general, Hopf duality interchanges the two properties), and \( L^* \) is not linearized (unlike \( L \)). The antipode in \( L^* \) is the same as that in \( L \) (a general property of duality for any commutative or cocommutative Hopf monoid).

Henceforth, product, coproduct, and antipode on linear orders will always be taken to mean the operations of \( L^* \) rather than \( L \).

For later use, we calculate the composition \( \mu_A \circ \Delta_A \) for any \( A \subseteq I \). Say that two linear orders \( u, w \in \ell[I] \) are A-consistent, written \( u \approx_A w \), if all pairs of elements in the same block of \( A \) appear in the same order in \( u \) and \( w \); that is, if \( i \equiv_A j \) then \( u(i) < u(j) \) if and only if \( w(i) < w(j) \). For example, if \( A = 13|2 \), then \( \{312, 321, 231\} \) is an equivalence class under \( \approx_A \). Then
\[
\mu_A(\Delta_A(w)) = \begin{cases} \sum_{u \in \ell[I] : u \approx_A w} u & \text{if } A \subseteq W, \\ 0 & \text{otherwise}. \end{cases} \tag{2.15}
\]

The following definition will also be useful. Recall [Sta12, §1.4] that \( i \in [n-1] \) is a (right) descent of a permutation \( v \in S_n \) if \( v(i) > v(i+1) \). The set of descents of \( v \) is denoted by \( \text{Des}(v) \), and the number of descents is \( \text{des}(v) \).

**Definition 2.9.** Let \( w, u \) be linear orders on \( I \). The \( u \)-descent composition of \( w \) is the coarsening \( D(w, u) \) of \( W = w(1) \cdots w(n) \) whose separators correspond to descents of the permutation \( u^{-1}w \); equivalently, \( w(i) \equiv w(i + 1) \) if and only if \( i \notin \text{Des}(u^{-1}w) \).

For example, suppose \( I = \{a, b, c, d, e, f, g, h\} \) and let \( w = \text{aebfcdhg}, w = \text{bdahfgce} \in \ell[I], \) so that \( u^{-1}w = \text{38 \cdot 157 \cdot 246} \) (with the descents marked by dots). Then \( D(w, u) = \text{ae|bfc|dgh} = \text{ae|bfc|dgh}. \)

Descent compositions have the following basic properties:
\[
D(w, u) = A_0 \iff u = w; \tag{2.16}
\]
\[
\forall A \subseteq W : u \approx_A w \iff D(w, u) \subseteq A; \tag{2.17}
\]
\[
\dim \sigma_{D(w,u)} = |D(w,u)| = \text{des}(u^{-1}w) + 1. \tag{2.18}
\]
In light of (2.17), we can usefully rewrite (2.15) (when $A = A_1|\cdots|A_k$ is $w$-natural) as

$$\mu_A(\Delta_A(w)) = \sum_{u \in \text{Shuffle}(A_1,\ldots,A_k)} u = \sum_{u \in \ell[I]} u. \quad (2.19)$$

where

$$E_{w,u} = \{A \in [n] : D(w, u) \leq A \leq W\}. \quad (2.20)$$

**Mat: Matroids.** Let Mat$I$ be the $k$-vector space spanned by all matroids with ground set $I$ (see Section 2.2). To make the vector species Mat into a Hopf monoid, we define a product by

$$\mu_{I,J}(M_1 \otimes M_2) = M_1 \oplus M_2 \quad (2.21a)$$

for every pair of matroids $M_1, M_2$ on disjoint ground sets $I, J$ respectively. The coproduct $\Delta_{I,J}$ is defined by

$$\Delta_{I,J}(M) = M|I \otimes M/I \quad (2.21b)$$

where $M|I$ is the restriction to $I$ (also known as the deletion of $J$, the complement of $I$) and $M/I$ is the contraction of $I$; in particular, Mat is commutative but not cocommutative.

Recall that the (independence complex of) the contraction $M/I$ is the link of any facet of $M|I$; the choice of facet does not matter. In fact, as we now prove, this property characterizes matroids. The proof is not difficult, but to the best of our knowledge this characterization of matroids has not previously appeared in the literature.

**Theorem 2.10.** Let $\Gamma$ be a simplicial complex on ground set $E$. Then $\Gamma$ is a matroid complex if and only if it has the property of link invariance: for every $X \subseteq E$ and every facets $\sigma, \tau \in \Gamma|E$ we have $\text{link}_\Gamma(\sigma) = \text{link}_\Gamma(\tau)$.

**Proof.** $(\implies)$ First, note that $\text{link}_\Gamma(\sigma)$ and $\text{link}_\Gamma(\tau)$ are both simplicial complexes on $Y = X \setminus E$, because $\sigma, \tau$ are facets (not just arbitrary faces) of $\Gamma|X$. Moreover, they are pure, since links in pure complexes are pure. By symmetry between $\sigma$ and $\tau$, it is enough to show that every facet of $\text{link}_\Gamma(\sigma)$ is a face of $\text{link}_\Gamma(\tau)$. Accordingly, let $\alpha$ and $\beta$ be facets of $\text{link}_\Gamma(\sigma)$ and $\text{link}_\Gamma(\tau)$ respectively, so that $\sigma \cup \alpha$ and $\tau \cup \beta$ are facets of $\Gamma$. We will show that in fact $\alpha \in \text{link}_\Gamma(\tau)$. If $\alpha = \beta$ then there is nothing to prove; otherwise, we induct on the size of the symmetric difference $|\beta \Delta \alpha|$. Let $v \in \beta \setminus \alpha$; by basis exchange there exists $w \in (\sigma \cup \alpha) \setminus (\tau \cup \beta) = (\sigma \setminus \tau) \cup (\alpha \setminus \beta)$ such that $(\tau \cup \beta) - v + w = \tau \cup (\beta - v) + w$ is a facet of $\Gamma$. In particular $\tau + w$ is a face, so it cannot be the case that $w \in \sigma \setminus \tau$ (otherwise $\tau$ would not be a facet of $\Gamma|A$). Therefore $w \in \alpha \setminus \beta$ and the new facet is $\tau \cup \beta'$, where $\beta' = \beta - v + w$. Thus $|\beta' \Delta \alpha| = |\beta \setminus \alpha| - 1$ and the result follows by induction.

$(\Leftarrow)$ Suppose that $\Gamma$ is not a matroid complex; then there is some $X \subseteq E$ such that $\Gamma|X$ is not pure. Let $\sigma, \tau$ be facets of $\Gamma|X$ of different cardinalities, say $|\sigma| < |\tau|$. We may assume WLOG that $X = \sigma \cup \tau$. Let $d = \dim \sigma$ and Let $\tau = \{v_1, \ldots, v_i\}$. For $0 \leq i \leq k$, define $X_i = \sigma \cup \{v_1, \ldots, v_i\}$ and $\Gamma_i = \Gamma|X_i$. Then

$$\langle \sigma \rangle = \Gamma_0 \subsetneq \Gamma_1 \subsetneq \cdots \subsetneq \Gamma_k = \Gamma|X$$

and $\dim \Gamma_0 = \dim \Gamma_1 = d < \dim \Gamma_k$. Let $j$ be the smallest index such that $\dim \Gamma_j > d_0$ (necessarily, $\dim \Gamma_j = d + 1$) and let $\phi$ be a facet of $\Gamma_j$ such that $\dim \phi = d + 1$. Then $\phi$ must contain $v_j$, so $\phi' = \phi - v_j$ is a face of $\Gamma_{j-1}$, hence a facet (since $\dim \Gamma_{j-1} = d = \dim \phi'$). On the other hand, $\sigma$ is also a facet of $\Gamma_{j-1}$ (since it is a facet of $\Gamma_k$), and $x_j$ belongs to $\text{link}_\Delta(\phi')$ but not to $\text{link}_\Delta(\sigma)$. □
Corollary 2.11. Mat is the largest subspecies of SC that admits a Hopf monoid structure with the operations (2.21a) and (2.21b).

GP and GP+: Generalized permutohedra. Let GP[I] be the k-vector space spanned by all generalized permutohedra in R^{I}. To make the vector species GP into a Hopf monoid, we define a product by
\[ \mu_{I,J}(p_1 \otimes p_2) = p_1 \times p_2 \]  
(2.22)
where \( p_1 \in \text{GP}[I] \) and \( p_2 \in \text{GP}[J] \); it was noted in §2.4 that the product is a generalized permutohedron. The coproduct \( \Delta_{I,J} \) is given by
\[ \Delta_{I,J}(p) = p|I \otimes p/I \]  
(2.23)
where the polytopes on the right-hand-side are defined by (2.8). It follows from the definitions that for any \( A \vdash I \) and \( p \in \text{GP}[I] \) we have \( \mu_A(\Delta_A(p)) = p_A \). The antipode in GP was computed by Aguiar and Ardila [AA17, Thm. 7.1] using topological methods:
\[ s^{GP}(p) = (-1)^{|I|} \sum_{q \subseteq p} (-1)^{\text{codim} q} q. \]  
(2.24)

The Hopf monoid \( \text{GP}_+ \) is defined by setting \( \text{GP}_+[I] \) to be the k-vector space spanned by all extended generalized permutohedra in R^{I}. The product and coproduct are defined in the same way as for GP [AA17, §5.3], with the proviso that \( \Delta_{I,J}(p) = 0 \) if \( p \in \text{GP}[I,J] \) is undefined (i.e., if the linear functional \( 1_I \) is unbounded from above on \( p \)). That is,
\[ \mu_A(\Delta_A(p)) = \begin{cases} p_A & \text{if the linear functional } 1_I \text{ is bounded from above on } p, \\ 0 & \text{otherwise.} \end{cases} \]  
(2.25)

The map \( \text{Mat} \to \text{GP} \) sending \( M \) to its base polytope \( p_M \) is an injective morphism of Hopf monoids [AA17, Thm. 12.3(4), Thm. 12.4, Prop. 14.3]. The antipode in Mat is best understood via the embedding Mat \( \to \text{GP} \); see [AA17, Theorem 14.4].

3. Hopf classes of ordered complexes

3.1. Definitions and basic properties. An ordered complex is a triple \((w, \Gamma, I)\) where \( \Gamma \) is a simplicial complex on finite vertex set \( I \), and \( w \) is a linear order on \( I \). If the ground set is clear from context, we may write simply \((w, \Gamma)\).

For an initial segment \( A \) of \( w \), the (initial) restriction and (initial) contraction of \((w, \Gamma)\) with respect to \( A \) are defined as \((w, \Gamma)|A = (w|_A, \Gamma|A, A)\) and \((w, \Gamma)/A = (w|_{I \setminus A}, \Gamma/A, I \setminus A)\), where \( \Gamma/A = \text{link}_\Gamma(\varphi) \), where \( \varphi \) is the facet of \( \Gamma|A \) that is lex-minimal with respect to \( w \).

Note that restricting to the entire ground set (as an initial segment), or contracting the empty initial segment, leaves \((w, \Gamma)\) unchanged, while restricting to the empty set or contracting the empty initial segment produces the trivial ordered complex \((\emptyset, \{\emptyset\}, \emptyset)\), where \( \emptyset \) denotes the (trivial) ordering of the empty set and \( \{\emptyset\} \) is the trivial simplicial complex (not the void complex!).

Initial restriction and contraction behave well when iterated (analogously to deletion and contraction for matroids; see [Oxl11, Prop. 3.1.26]), in the following sense.

Lemma 3.1. Let \((w, \Gamma)\) be an ordered complex, and suppose that \( I \) and \( I \sqcup J \) are initial segments of \( w \). Then the following restriction/contraction relations hold:

(i) \((w, \Gamma)|I = ((w, \Gamma)|(I \sqcup J))|I.\)
We define the ordered join
\[ \phi \text{Init} \]
shuffle of the orderings of the join factors will do. Accordingly, for any setting, we need to specify in addition an ordering on the ground set of the join; any observation that the lex-minimal facet
\[ \text{link} \]
link
\[ \text{Proof.} \]

\[ \text{Let} \]\n\[ \text{Lemma 3.2.} \]
ordered join provides a product, and initial restriction and contraction provide a coproduct.

\[ \text{Definitions} \]
\[ \text{of ordered complexes is called a \textit{Hopf class} if it satisfies the following three conditions.} \]

(1) \textbf{(Closure under ordered join)} If \((w_1, \Gamma_1), (w_2, \Gamma_2) \in H\), then \((w_1, \Gamma_1) \ast (w_2, \Gamma_2) \in H\) for every \(w \in \text{Shuffle}(w_1, w_2)\).

(2) \textbf{(Closure under initial restriction)} If \((w, \Gamma) \in H\) and \(A\) is an initial segment of \(w\), then \((w, \Gamma) / A \in H\).

(3) \textbf{(Closure under initial contraction)} If \((w, \Gamma) \in H\) and \(A\) is an initial segment of \(w\), then \((w, \Gamma) / A \in H\).

We will show (Theorem 3.16) that every Hopf class gives rise to a Hopf monoid: ordered join provides a product, and initial restriction and contraction provide a coproduct.

Pure simplicial complexes do not form a Hopf class, since they are not closed under restriction (although they are closed under contraction and join). We say that a pure ordered complex is \textbf{prefix-pure} if all its initial restrictions (hence all its initial contractions) are pure. Evidently, if every complex in a Hopf class \(H\) is pure, then in fact every complex in \(H\) is prefix-pure. (In fact this condition appears in Brylawski’s fundamental paper [Bry77] on broken-circuit complexes, although it does not play a major role there.)

\[ \textbf{Proposition 3.4.} \] The class \(\text{PRE}\) of all prefix-pure complexes is a Hopf class, hence the unique largest Hopf class whose members are all pure complexes.

\[ \text{Proof.} \] The definition of prefix-purity implies that \(\text{PRE}\) is closed under initial restriction, and it is closed under initial contraction because every link in a pure complex is pure.
Moreover, if \((w_1, \Gamma_1)\) and \((w_2, \Gamma_2)\) are prefix-pure, then by Lemma 3.2 every initial restriction or contraction of an ordered join \((w_1, \Gamma_1) \star_w (w_2, \Gamma_2)\) is a join of initial restrictions or contractions of the two of them, hence is pure. Thus \text{PRE} is a Hopf class. \qed

Henceforth, we will only consider Hopf classes of prefix-pure complexes.

The intersection of Hopf classes is again a Hopf class. Therefore, every sub-collection \(H \subseteq \text{PRE}\) has a well-defined \textbf{Hopf closure} \(\bar{H}\), namely the intersection of all Hopf classes containing \(H\). We may also speak of the Hopf class \textbf{generated} by a collection of prefix-pure ordered complexes.

The unique smallest Hopf class, and in fact the only finite Hopf class, is the singleton class TRIV containing only the trivial ordered complex. Additional elementary examples are the classes OMAT of ordered matroid independence complexes, its subclass OUM of ordered independence complexes of uniform matroids (equivalently, skeletons of simplices), and the smaller subclass OSIM of all ordered simplices.

In the unordered setting, the largest class of pure simplicial complexes that is closed under join, restriction, and deletion is precisely the class of matroid complexes. Thus any Hopf class between OMAT and \text{PRE} can be regarded as an extension of matroids in the ordered setting. There are many Hopf classes that include non-matroidal complexes.

3.2. \textbf{A zoo of Hopf classes.}

\textbf{Example 3.5 (Strongly lex-shellable complexes).} A pure simplicial complex \(\Gamma\) is \textbf{shellable} if its facets can be ordered \(\varphi_1, \ldots, \varphi_n\) such that whenever \(j < i\), there is an index \(k < i\) and a vertex \(x \in \varphi_i\) such that

\[ \varphi_j \cap \varphi_i \subseteq \varphi_k \cap \varphi_i = \varphi_i \setminus \{x\}. \] (3.2)

There are equivalent definitions of shellability, but this is the most convenient for our purposes; see, e.g., [Bjo92, §7.2].

We say that a pure ordered complex \((w, \Gamma)\) is \textbf{lex-shellable}\(^6\) if the lexicographic order \(\prec_w\) on facets of \(\Gamma\) induced by \(w\) is a shelling order. We define \((w, \Gamma)\) to be \textbf{strongly lex-shellable} if it is prefix-pure and every restriction to an initial segment is lex-shellable. Strong lex-shellability is more restrictive than lex-shellability: for example, the graph with edges 12, 14, 34 and the natural ordering on vertices is lex-shellable but not strongly lex-shellable. On the other hand, Hopf classes are closed under restriction to initial segments, so if every element of a Hopf class \(H\) is lex-shellable then in fact every element is strongly lex-shellable.

\textbf{Remark 3.6.} Lex-shellability in this sense is a stronger condition than shellability. We carried out a brute-force computation using Sage [S\textsuperscript{+}20] to check that the boundary of Lockeberg’s simplicial 4-polytope [Hac01, KK87, Loc77], with 12 vertices and 48 facets, is not lex-shellable. We do not have a computer-free proof of this observation, nor do we have any reason to believe that this example is minimal.

The class SLS of all strongly lex-shellable complexes is a Hopf class, for the following reasons. First, it is closed under restriction by definition, and it is closed under contraction because shelling orders on \(\Gamma\) restrict to shelling orders on all its links, and restricting a

\(^6\)This definition of lex-shellability is not to be confused with CL- or EL-shellability of the order complex of a poset as in, e.g., [Bjo80, BW82].
lex-shelling to a final segment produces a lex-shelling. It remains to check closure under ordered join.

Let \((w_1, \Gamma_1, I_1), (w_2, \Gamma_2, I_2) \in \text{SLS}\) and let \(w \in \text{Shuffle}(w_1, w_2)\). Let \(\varphi = \varphi_1 \cup \varphi_2\) and \(\psi = \psi_1 \cup \psi_2\) be facets of \(\Gamma_1 \ast \Gamma_2\), with \(\varphi_i, \psi_i \in \Gamma_i\), such that \(\psi \leq_w \varphi\). Then either \(\psi_1 \leq_w \varphi_1\) or \(\psi_2 \leq_w \varphi_2\); assume without loss of generality that the first case holds. Since restricting \(\leq_w\) to \(I_1\) gives a shelling order of \(\Gamma_1\), it follows that \(\Gamma_1\) has a facet \(\rho_1 \leq_w \varphi_1\) and a vertex \(x \in \varphi_1\) such that \(\psi_1 \cap \varphi_1 \subseteq \rho_1 \cap \varphi_1 = \varphi_1 \setminus \{x\}\). Then it is routine to check that \(\rho = \rho_1 \cup \varphi_2\) satisfies (3.2), verifying that \((w_1, \Gamma_1) \ast (w_2, \Gamma_2) \in \text{SLS}\).

Not every prefix-pure complex is shellable. For example, Ziegler [Zie98] constructed a non-shellable 3-dimensional ball \(Z\) with 10 vertices and 21 facets. According to computation with Sage, \(Z\) is prefix-pure under 6528 of the 10! = 3628800 possible vertex orderings.

**Example 3.7 (Shifted complexes).** An ordered simplicial complex \((w, \Gamma, I)\) is **shifted** if, whenever \(\gamma \in \Gamma\) and \(e \in \gamma\), then \(\gamma \cup f \setminus e\) is a face for every \(f \leq_w e\). When \(\Gamma\) is pure of dimension \(d-1\), this is equivalent to the statement that the facets of \(\Gamma\) form an order ideal in Gale order, which is the following partial order on \(\binom{\Gamma}{d}\): for \(\varphi, \psi \in \binom{\Gamma}{d}\) with \(\varphi = \{f_1 \leq_w \cdots \leq_w f_d\}\) and \(\psi = \{g_1 \leq_w \cdots \leq_w g_d\}\) we have

\[
\varphi \leq_g \psi \iff f_i \leq_w g_i \forall i.
\]

In fact Gale order on \(\binom{\Gamma}{d}\) is a distributive lattice, isomorphic to the principal order ideal generated by a \(d \times (|I| - d)\) rectangle in Young’s lattice of integer partitions. For more detail, see §6.3.

Initial restrictions and initial contractions of shifted complexes are easily seen to be shifted. However, pure shifted complexes are not closed under ordered join and therefore do not form a Hopf class. Nevertheless, the class of ordered joins of shifted complexes is a Hopf class \(\text{SHIFT}\), because join is compatible with initial restriction and contraction (Lemma 3.2).

**Example 3.8 (Quasi-matroidal classes).** The quasi-matroidal classes studied in [Sam20] are defined as Hopf classes that satisfy additional conditions: a quasi-matroidal class must contain all ordered matroids and shifted complexes, and be closed under taking links of arbitrary faces (not just initial segments). The unique smallest quasi-matroidal class is \(\text{QMIN} = \text{OMAT} \cup \text{SHIFT}\). The unique largest quasi-matroidal class \(\text{PURE} [\text{Sam20, Example 3.3}]\) is defined recursively as follows: \((w, \Gamma, I) \in \text{PURE}\) if either \(\Gamma\) has exactly one facet, or both the following conditions hold:

- \((w|_I, \Gamma|I') \in \text{PURE}\), where \(I'\) is obtained by deleting the \(w\)-maximal non-cone vertex; and
- \((w|_F, \text{link}_F(F)) \in \text{PURE}\) for every \(F \in \Gamma\).

All complexes in \(\text{PURE}\) are vertex-decomposable [Sam20, Thm. 3.5], hence shellable; on the other hand, Hopf classes can contain non-shellable complexes, such as Ziegler’s non-shellable ball \(Z\).

The quasi-matroidal classes \(\text{QI}, \text{QE}, \) and \(\text{QC}\) are defined by the quasi-independence, quasi-exchange, and quasi-circuit axioms respectively [Sam20, Defn. 4.1]. None of these classes is contained in another one [Sam20, Thm. 4.3], so each strictly contains \(\text{SHIFT}\) and is strictly contained in \(\text{PURE}\).
Example 3.9 (Gale truncations). Let \((w, \Gamma, I)\) be a pure ordered complex of dimension \(d - 1\) and let \(J \subseteq \binom{I}{d}\) be an order ideal in Gale order (see Example 3.7). The Gale truncation of \((w, \Gamma)\) at \(J\) is \((w, \Gamma_J)\), where \(\Gamma_J\) is the (pure) subcomplex of \(\Gamma\) generated by the facets in \(J\). Gale truncations generalize shifted complexes, because a shifted complex is just a Gale truncation of an ordered uniform matroid. In fact, \(\text{SHIFT}\) is the Hopf class of all Gale truncations of direct sums of ordered uniform matroids.

According to computation with Sage [S+20], there exists at least one vertex order \(w\) on Ziegler’s non-shellable ball \(Z\) such that \((w, Z)\) is prefix-pure, but not all Gale truncations are prefix-pure. Thus Gale truncation is not a well-defined operation on Hopf classes in general. On the other hand, by [Sam20, Theorem 4.11], the class \(\text{QE}\) is closed under Gale truncations, so for any Hopf class \(H \subset \text{QE}\), the collection of Gale truncations of elements of \(H\) generates a Hopf class \(H^{\text{Gale}}\) such that \(H \subseteq H^{\text{Gale}} \subseteq \text{QE}\).

Example 3.10 (Matroid threshold complexes). Let \(\Gamma\) be a matroid independence complex on ground set \(I\), let \(\ell\) be a generic linear functional on \(\mathbb{R}^I\), and let \(r \in \mathbb{R}\). Such a generic \(\ell\) induces a linear order \(w_{\ell}\) on \(I\) defined by \(i < j\) iff \(\ell(e_i) < \ell(e_j)\). Let \(\Gamma(\ell, r)\) be the subcomplex of \(\Gamma\) generated by the facets \(\varphi\) such that \(\ell(\varphi) \leq r\). We call \(\Gamma(\ell, r)\) a matroid threshold complex; by the proof of [HS20, Thm. 2(B)], it is a Gale truncation of \((w_{\ell}, \Gamma)\). Thus, if \(H \subset \text{OMAT}\), then the class of matroid threshold complexes of elements of \(H\) generates a Hopf class \(H^{\text{thr}} \subset H^{\text{Gale}} \subset \text{OMAT}^{\text{Gale}} \subseteq \text{QE}\).

When \(\Gamma\) is a simplex skeleton, the definition of matroid threshold complex reduces to the usual definition of a threshold complex (see, e.g., [KR08]). Therefore, the class \(\text{OUTH}^{\text{thr}}\) is the smallest Hopf class containing all threshold complexes.

Example 3.11 (Color-shifted complexes). Color-shifted complexes generalize pure shifted complexes (which arise as the case \(k = 1\)). They were introduced by Babson and Novik [BN06]; see also [DKM16, §4.4]. A simplicial complex \(\Gamma\) is color-shifted if its vertices can be partitioned into disjoint sets \(I_1, \ldots, I_k\) ("color classes") with the following properties:

1. There is a "palette vector" \(a = (a_1, \ldots, a_k) \in \mathbb{N}^k\) such that every facet of \(\Gamma\) has exactly \(a_i\) vertices of color \(i\). (That is \(\Gamma\) is "\(a\)-balanced"; this condition was introduced in [Sta79].)
2. The color classes are equipped with linear orders \(w_1, \ldots, w_k\), with the following property: if \(x, y\) both have color \(j\) with \(x <_{w_j} y\), and \(\gamma \in \Gamma\) contains \(y\) but not \(x\), then \(\gamma \setminus \{y\} \cup \{x\} \in \Gamma\).

Note that when \(k = 1\), the definition reduces to that of a pure shifted complex.

We define an ordered complex \((w, \Gamma, I)\) to be color-shifted if there exists a partition \(I = I_1 \sqcup \cdots \sqcup I_k\) and orderings \(w_1, \ldots, w_k\) such that \(\Gamma\) is color-shifted in the above sense and \(w \in \text{Shuffle}(w_1, \ldots, w_k)\). This property is easily seen to be preserved by initial restriction, initial contraction, and ordered join. Thus color-shifted complexes constitute a Hopf class \(\text{COLOR}\).

Evidently \(\text{SHIFT} \subseteq \text{COLOR}\). In fact, this inclusion is strict. Let \(I_1 = \{x_1, y_1\}\) and \(I_2 = \{x_2, y_2\}\) and \(\Gamma = \langle x_1 x_2, x_1 y_2, y_1 x_2 \rangle\). This complex is color-shifted under the orderings \(x_i <_{w_i} y_i\), but it is join-irreducible and is not shifted with respect to any ordering on \(I_1 \cup I_2\).

The inclusions \(\text{COLOR} \subseteq \text{QE}\) and \(\text{COLOR} \subseteq \text{QI}\) can be proven by adapting the relevant parts of the proof of [Sam20, Thm. 4.2] from shifted to color-shifted complexes \(\text{mutatis} \)
mutandis. Both inclusions are strict because matroid complexes are in general not color-shifted. We suspect that \( \text{COLOR} \nsubseteq \text{QC} \) (the proof from [Sam20] does not carry over to the color-shifted setting).

\[\text{Example 3.12 (Broken-circuit complexes).} \] Let \((w, \Gamma, I)\) be an ordered matroid complex. Recall that a circuit of the corresponding matroid is a minimal non-face of \(\Gamma\). A broken circuit is a set of the form \(C \setminus \min_w(C)\), where \(C\) is a circuit. The unreduced broken-circuit complex \(BC_w(\Gamma)\) consists of all subsets of \(I\) containing no broken circuit. This complex is always a cone over the first vertex \(x_1\) of \(w\); the base of the cone is called the reduced broken-circuit complex \(\overline{BC}_w(\Gamma)\). Both \(BC_w(\Gamma)\) and \(\overline{BC}_w(\Gamma)\) are pure [Bjö92, Prop. 7.4.2] and lex-shellable [Bjö92, Thm. 7.4.3]. Reduced broken-circuit complexes are prefix-pure [Bry77, Prop. 4.4]; more strongly, one can see that \(BC_w(\Gamma)|A = \overline{BC}_w(\Gamma)|A\) for every \(A \in \text{Init}(w)\), so \(BC_w(\Gamma)\) is strongly lex-shellable, and this property is preserved by deconing. Reduced broken-circuit complexes do not form a Hopf class because they are not closed under contractions of initial segments, but they generate a Hopf subclass \(\text{BC} \subseteq \text{SLS}\). Moreover, the class of broken-circuit complexes strictly includes that of matroid complexes [Bry77, Thm. 4.2, Rmk. 4.3], so \(\text{OMAT} \nsubseteq \text{BC}\).

We summarize the hierarchy of Hopf classes of prefix-pure complexes as follows.

\[\text{Proposition 3.13.} \] The Hopf classes described above are ordered by inclusion as in Figure 2.

\[\text{Figure 2.} \] The hierarchy of Hopf classes of prefix-pure complexes. Solid lines indicate inclusions known to be strict; dashed lines indicate possible equalities. All classes are described in §§3.1–3.2, except \(\text{OMAT}^+\), which will be described in §5.3.
Conjecture 3.14. $BC \subset \text{OMAT}^\text{gale} \subset \text{QE} \cap \text{QI}$.

The first inclusion in Conjecture 3.14 is very close to [CS, Thm. 1.4], which states that every broken-circuit complex is an order ideal in Las Vergnas’ internal activity poset (see [LV01, Thm. 3.4]), whose relations are all relations in Gale order. The conjecture is true when $\Gamma$ is shifted, since then its broken-circuit complex is also shifted [Kli, Thm. 5]. Moreover, the $f$-vectors of broken-circuit complexes are more constrained than those of shifted complexes, for the following reasons. Pure shifted complexes are shellable, hence Cohen-Macaulay; on the other hand, the Cohen-Macaulay property and the $f$-vector are preserved by algebraic shifting [Kal02, §4.1], so the $f$-vectors of pure shifted complexes coincide with those of Cohen-Macaulay complexes and satisfy the so called $M$-sequence inequalities. On the other hand, $f$-vectors of broken circuit complexes form a much smaller class. As discussed in [CS, Section 4], the family of $h$-vectors of broken-circuit complexes with $d$ positive entries and last entry $k$ is finite, while for Cohen-Macaulay complexes, and hence shifted complexes, it is infinite.

The discussion in Example 3.9 implies $\text{OMAT}^\text{gale} \subseteq \text{QE}$, and moreover $\text{OMAT}^\text{gale} \subseteq \text{QI}$ by [Sam20, Thm. 5.8]. Since $\text{QE}$ and $\text{QI}$ are incomparable, both these inclusions are strict.

We expect that the axioms for $\text{QE}$ and $\text{QI}$ are too loose to capture all Gale truncations of matroids. We note that this conjecture cannot be proved on the level of $f$-vectors, since all simplicial complexes in $\text{QE} \times \text{QI}$ are shellable, and $\text{OMAT}^\text{gale}$ contains all shifted complexes, hence all Cohen-Macaulay $f$-vectors by the discussion above.

Conjecture 3.15. $\text{OMAT}_+ \subseteq \text{SLS}$.

It was proven in [HS20, Thm. 2(A)] that every generic real-valued function on the ground set of a matroid, when extended linearly to bases, gives rise to a shelling order on the independence complex. A proof of Conjecture 3.15 might proceed along similar lines.

3.3. Hopf monoids from Hopf classes. We now show that every Hopf class $H$ naturally gives rise to a Hopf monoid $H$. Define a set species $h[I]$ to be the set of all ordered complexes in $H$ on ground set $I$, and let $H$ be the corresponding vector species. Observe that these species are connected, since $h[\emptyset]$ contains only the trivial ordered complex; this gives rise to a unit $u$ and a counit $\epsilon$. We define a Hopf product $\mu_{I,J}$ and coproduct $\Delta_{I,J}$ on basis elements by join and restriction/contraction respectively:

$$
\mu_{I,J}((w_1, \Gamma_1) \otimes (w_2, \Gamma_2)) = \sum_{w \in \text{Shuffle}(w_1, w_2)} (w_1, \Gamma_1) * (w_2, \Gamma_2),
$$  
(3.3a)

$$
\Delta_{I,J}(w, \Gamma) = \begin{cases} 
(w|_I, \Gamma|I) \otimes (w|_J, \Gamma/I) & \text{if } I \text{ is an initial segment of } w, \\
0 & \text{otherwise.}
\end{cases}
$$  
(3.3b)

Theorem 3.16. For every Hopf class $H$, the tuple $(H, \mu, u, \Delta, \epsilon)$ is a connected Hopf monoid.

Proof of Theorem 3.16. Most of the Hopf monoid axioms (see §2.5) are straightforward; the only ones that require substantial proof are coassociativity (2.10) and compatibility (2.11).

First, we check coassociativity. Let $(w, \Gamma, I)$ be an ordered complex and $I = A \sqcup B \sqcup C$. For the sake of legibility, we drop disjoint union symbols: e.g., $AB = A \sqcup B$. If $A$ and $AB$ are not both initial segments of $w$, then

$$
(\Delta_{A,B} \otimes \text{Id}) \circ \Delta_{AB,C}(w, \Gamma) = (\text{Id} \otimes \Delta_{B,C}) \circ \Delta_{A,BC}(w, \Gamma) = 0.
$$
On the other hand, if $A$ and $AB$ are both initial segments, then
\[
\begin{align*}
\Delta_{A,B} \otimes \text{Id}_C \left( \Delta_{AB,C}(w, \Gamma) \right) &= (w, \Gamma)|AB|A \otimes (w, \Gamma)|AB/A \otimes (w, \Gamma)/AB, \\
\text{Id}_A \otimes \Delta_{B,C}(\Delta_{A,BC}(w, \Gamma)) &= (w, \Gamma)|A \otimes (w, \Gamma)/A|B \otimes (w, \Gamma)/A/B,
\end{align*}
\]
and by Lemma 3.1 the two expressions coincide.

Second, we check compatibility. Let $(w_1, \Gamma_1, AB)$ and $(w_2, \Gamma_2, CD)$ be ordered complexes, and for short let $\xi$ denote their tensor product in $H[AB] \otimes H[CD]$. If either $A \notin \text{Init}(w_1)$ or $C \notin \text{Init}(w_2)$, then $\Delta_{A,B} \times \Delta_{C,D}(\xi) = 0$, and in addition $AC$ is not an initial segment of any shuffle of $w_1$ and $w_2$, so $\Delta_{AC,BD}(\mu_{AB,CD}(\xi)) = 0$ as well.

On the other hand, suppose that $A \in \text{Init}(w_1)$ and $C \in \text{Init}(w_2)$. Notice that if $w$ is in $\text{Shuffle}(w_1, w_2)$, then $\Delta_{AC,BD}((w_1, \Gamma_1) * (w_2, \Gamma_2))$ is non-zero only if $AC \in \text{Init}(w)$. Hence
\[
\begin{align*}
\Delta_{AC,BD}(\mu_{AB,CD}(\xi)) &= \sum_{w \in \text{Shuffle}(w_1, w_2)} \Delta_{AC,BD}((w_1, \Gamma_1) * (w_2, \Gamma_2)) \\
&= \sum_{w \in \text{Shuffle}(w_1, w_2) : \text{AC} \in \text{Init}(u)} \left( (w_1, \Gamma_1)|AC \ast (w_2, \Gamma_2)|AC \right) \otimes \left( (w_1, \Gamma_1)/AC \ast (w_2, \Gamma_2)/AC \right).
\end{align*}
\]
(3.4)

Meanwhile, the other side of the compatibility diagram (2.11) yields
\[
(\mu_{A,C} \otimes \mu_{B,D}) \circ \tau \circ (\Delta_{A,B} \otimes \Delta_{C,D})(\xi) = \mu_{A,C} \otimes \mu_{B,D} \left( (w_1, \Gamma_1)|A \otimes (w_2, \Gamma_2)|C \otimes (w_1, \Gamma_1)/A \otimes (w_2, \Gamma_2)/C \right)
\]
\[
= \sum_{u \in \text{Shuffle}(w_1/A, w_2/C)} \left( (w_1, \Gamma_1)|A \ast (w_2, \Gamma_2)|C \right) \otimes \left( (w_1, \Gamma_1)/A \ast (w_2, \Gamma_2)/C \right). \tag{3.5}
\]

In fact, the index sets of the two sums (3.4) and (3.5) are in bijection: $w$ in the former may be taken to be the concatenation of $u$ and $v$ in the latter. Moreover, the summands are equal by Lemma 3.2, completing the proof of compatibility. \qed

Of particular interest to us are the Hopf monoids $\text{Pre} = \text{PRE}^3$ (the largest Hopf monoid of pure ordered simplicial complexes in which we can work) and $\text{OMat} = \text{OMAT}^3$.

**Proposition 3.17.** There is an isomorphism of Hopf monoids $\text{OMat} \cong L^* \times \text{Mat}$. 

**Proof.** In both cases the basis elements are matroid complexes equipped with an ordering of the ground set, giving equality on the level of vector species. Moreover, the product and coproduct defined on $\text{OMat}$ by (3.3a) and (3.3b) coincide with the Hopf operations on $L^* \times \text{Mat}$ defined by (2.14a) and (2.21a) (product) and (2.14b) and (2.21b) (coproduct). \qed

**Proposition 3.18.** If $H$ is a Hopf class containing $\text{OMAT}$, then the map $\text{OMat} \rightarrow H$ given by $(w, M) \mapsto (w, I(M))$ is a Hopf monoid monomorphism. 

**Proof.** For independence complexes of matroids, the product and coproduct in $H$ coincide with those in $\text{OMat}$, so it is immediate that the thus the monomorphism of Hopf monoids is clear. \qed
Having shown that every Hopf class $H$ gives rise to a Hopf monoid $H$, we now want to find a cancellation-free formula for the antipode in $H$ in terms of the combinatorics of $H$. We start by focusing on Hopf classes with inherent geometry, such as OMAT, where we can hope to express the coefficients of the antipode as appropriate Euler characteristics, as in [AA17]. In order to do this, we may as well work in the more general setting of ordered generalized permutohedra.

As stated in the introduction, [GGMS87, Thm. 4.1] states that a polyhedron $p \subset \mathbb{R}^I$ is a matroid base polytope for some matroid on $I$ if and only if $p$ satisfies the following three conditions:

(M1) $p$ is bounded;
(M2) $p$ is an 0/1-polyhedron;
(M3) Every edge of $p$ is parallel to some $e_i - e_j$, where $\{e_i\}_{i \in I}$ is the standard basis of $\mathbb{R}^I$.

Conditions (M1) and (M3) together define the class of generalized permutohedra (see §2.4), while (M3) alone defines extended generalized permutohedra. In order to stay within the realm of Hopf classes of ordered simplicial complexes, we must retain condition (M2). In §5, we will study the Hopf class of ordered simplicial complexes arising from possibly-unbounded polyhedra satisfying conditions (M2) and (M3).

Definition 4.1. An ordered generalized permutohedron is a pair $(w, p)$, where $p \subset \mathbb{R}^I$ is a generalized permutohedron and $w$ is a linear order on $I$. The Hopf monoid of ordered generalized permutohedra is the Hadamard product $\text{OGP} = L^* \times \text{GP}$.

Like both $L^*$ and GP, the monoid OGP is commutative but not cocommutative. Since $L^*$ is not linearized as a Hopf monoid, neither is OGP. The inclusion $\text{Mat} \hookrightarrow \text{GP}$ gives rise to an inclusion $\text{OMat} \hookrightarrow \text{OGP}$, where $\text{OMat} = L^* \times \text{Mat}$, the Hopf monoid of ordered matroids.

Remark 4.2. It is also possible to study the Hopf monoid $L \times \text{GP}$. This monoid, unlike $L^* \times \text{GP}$, is a linearized Hopf monoid, so its antipode can be calculated using the methods of Benedetti and Bergeron [BB19]. Moreover, the projection map $\pi : L \times \text{GP} \to \text{GP}$ is a morphism of Hopf monoids, unlike the map $\pi^* : L^* \times \text{GP} \to \text{GP}$, which is only a morphism of vector species—if $w \otimes p \in \text{OGP}[I]$ and $v \otimes q \in \text{OGP}[J]$, then $\pi((w \otimes p) * (v \otimes q)) = p \times q$, but $\pi((w \otimes p) \ast (v \otimes q)) = \left(\frac{|I| + |J|}{|I|}\right)p \times q$.

On the other hand, $L \times \text{GP}$ is neither commutative nor cocommutative (since $L$ is co-commutative but not commutative), and does not arise from a Hopf class. In the ordered setting, deletion and contraction require splitting the ground set into an initial and a final segment, which corresponds to the coproduct in $L^*$. As we will see, another good property that $L^* \times \text{GP}$ enjoys but $L \times \text{GP}$ lacks is that its antipode is local in a precise geometric sense; see Proposition 7.4 and Remark 7.7.

The idea of ordering coordinates by forming a Hadamard product with $L^*$ carries over from generalized permutohedra to EGPs. However, the appropriate Hopf monoid to consider is not the full Hadamard product $L^* \times \text{GP}$, for the following reason. Suppose that $p \subset \mathbb{R}^I$ is an EGP in $\mathbb{R}^I$, and let $A \sqsupset I$. If the cone $\sigma_A$ belongs to the normal fan $\mathcal{N}_p$, then there is a well-defined face $p_A$ that maximizes the linear functionals in $\sigma_A$ (and if $A$
is a linear order, then \( p_\lambda \) is a vertex). However, if \( \sigma_Q \nsubseteq |N_p| \), then linear functionals in \( \sigma_A \) are unbounded on \( p \) and no such face exists. Accordingly, we define

\[
\ell_p[I] = \{ w \in \ell[I] : \sigma_{uv} \subseteq N_p \} = \{ w \in \ell[I] : p_{uv} \text{ is a well-defined vertex of } p \}. \quad (4.1)
\]

In particular, \( \ell_p[I] = \ell[I] \) if and only if \( p \) is bounded.

**Remark 4.3.** The reason to reverse the order is the following. To compute the restriction of \( p \) to the initial segment \( I \) we need to find the face of \( p \) maximized by the function \( 1_I \in \sigma_{J[I]} \), and the composition \( J|I \) is not refined by \( W \), but rather by \( W^{rev} \). Geometrically, this means that \( \sigma_{uv} \subseteq N_p \). Equivalently, linear functionals in \( \sigma_u \) are bounded from below on \( p \). (The reversal would not be necessary under the conventions in [AA17]; see the note in §2.3.)

**Lemma 4.4.** Let \( p \in \mathbb{R}^{I \cup J} \) be a generalized permutohedron. Then

\[
\{ w \in \ell_p[I \cup J] : w \in \text{Init}(w) \} = \{ uv : u \in \ell_{p[I]}[I], v \in \ell_{p[J]}[J] \}
\]

(4.2) where \( uv \) denotes the concatenation of \( u \) and \( v \).

**Proof.** We use the following basic fact about faces of polytopes [Stu96, eqn. (2.3), p.10]: for all linear functionals \( \lambda_{x_1}, \lambda_{x_2} \) on \( \mathbb{R}^{I \cup J} \), we have

\[
(\lambda_{x_1})_{x_2} = \lambda_{x_1 + \epsilon x_2}
\]

(4.3) for sufficiently small \( \epsilon > 0 \). We now prove (4.2) by double inclusion.

(\( \supseteq \)) Let \( u, v \) be as in the right hand side of (4.2) and let \( w = uv \). Then the face \( (p/I \times p/J)_{uv} = (p/I)_{uv} \) exists, because the functional \( \lambda_{uv} \) is bounded on \( p_{J[I]} \) by virtue of being bounded on each factor. Now let \( x_1 \in \sigma_{J[I]} \) and \( x_2 \in \sigma_{v_{rev}} \), then by (4.3) we have

\[
(p/I)_{uv} = (p/I)_{x_2} = p_{x_1 + \epsilon x_2}.
\]

The condition \( I \in \text{Init}(w) \) implies \( J/I \nwarrow W^{rev} \), so \( x_1 + \epsilon x_2 \in \sigma_{v_{rev}} \). Therefore \( p_{v_{rev}} \) is a vertex of \( p \), i.e., \( w \in \ell_p[I \cup J] \) as desired.

(\( \subseteq \)) Let \( w \) be such that \( \sigma_{v_{rev}} \subseteq N_p \) with \( I \in \text{Init}(w) \), and let \( u = w|_I \) and \( v = w|_J \). Since \( N_p \) is closed it contains \( C_{v_{rev}} \). Since \( J/I \nwarrow W^{rev} \), we have \( \sigma_{J[I]} \subseteq \sigma_{v_{rev}} \subseteq N_p \). Therefore, \( p \) has a face \( p_{J[I]} = p/I \times p/J \), on which \( \lambda_{v_{rev}} \) is bounded. Moreover, for \( (x, y) \in p/I \times p/J = p_{J[I]} \), we have \( \lambda_{v_{rev}}(x, y) = \lambda_u(x) + \lambda_v(y) \); in particular, \( \lambda_{u_{rev}} \) and \( \lambda_{v_{rev}} \) are both bounded on \( p/I \) and \( p/J \) respectively.

Accordingly, we define \( OGP_+ \) as a vector subspecies of \( L^* \times GP_+ \):

\[
OGP_+[I] = \langle w \otimes p : p \in GP_+[I], w \in \ell_p[I] \rangle.
\]

(4.4)

**Theorem 4.5.** \( OGP_+ \) is a Hopf submonoid of \( L^* \times GP_+ \).

**Proof.** It suffices to show that \( \mu_{I,J}(OGP_+[I] \otimes OGP_+[J]) \subseteq OGP_+[I \cup J] \) and \( \Delta_{I,J}(OGP_+[I \cup J]) \subseteq OGP_+[I] \otimes OGP_+[J] \), for all disjoint finite sets \( I, J \).

For the product, let \( u \otimes p \in OGP_+[I] \) and \( v \otimes q \in OGP_+[J] \), where \( I \cap J = \emptyset \). Then

\[
(u \otimes p)(v \otimes q) = \sum_{w \in \text{Shuffle}(u,v)} w \otimes (p \times q).
\]

(4.5) Every linear functional \( \lambda \) on \( \mathbb{R}^I \times \mathbb{R}^J \) is defined by \( \lambda(P, Q) = \lambda_I(P) + \lambda_J(Q) \). If \( w \in \text{Shuffle}(u, v) \) and \( \lambda \in \sigma_{v_{rev}} \), then \( \lambda_I \) (resp., \( \lambda_J \)) restricts to a functional in \( \sigma_{u_{rev}} \) (resp., \( \sigma_{v_{rev}} \)), respectively.
hence is maximized on $p$ (resp., $q$) at $p_{\text{rev}}$ (resp., $q_{\text{rev}}$). Hence $\lambda$ is maximized on $p \times q$ at $p_{\text{rev}} \times q_{\text{rev}}$. It follows that every summand in (4.5) belongs to $\text{OGP}_+[I \sqcup J]$.

For the coproduct, let $w \otimes p \in \text{OGP}_+[I \sqcup J]$. Then

$$\Delta_{I,J}(w \otimes p) = (w|_I \otimes p|_I) \otimes (w|_J \otimes p|_J).$$

Recall from (2.8) that $p|_I \times p/I$ is a face of $p$, so any linear functional $\lambda \in \sigma_{w_{\text{rev}}}$ is bounded above on $p$ and hence on $p|_I \times p/I$. The restriction of $\lambda$ to each element in the product is a pair of functionals, one in direction $w_{\text{rev}}|_I$ and another one in $w_{\text{rev}}|_J$, and each of those functionals is bounded above on $p|_I$ and $p/I$ respectively. \[\Box\]

**Theorem 4.6.** The symmetrization map $\text{Sym} : \text{GP}_+ \to \text{OGP}_+$ defined on $\text{GP}_+[I]$ by

$$\text{Sym}(p) = p^# = \sum_{w \in \ell_\text{p}[I]} w \otimes p$$

is an injective Hopf morphism. It restricts to a map $\text{GP} \to \text{OGP}$ given by $p^# = \sum_{w \in \ell[1]} w \otimes p$.

**Proof.** It is straightforward to check that $\text{Sym}$ is a morphism of vector species, so the proof reduces to checking that it that commutes with products and coproducts.

First, let $p \in \text{GP}_+[I], q \in \text{GP}_+[J]$, where $I, J$ are disjoint finite sets. We must show that $\mu_{\text{OGP}_+}(p^#, q^#) = (\mu_{\text{GP}_+}(p, q))^#$. Indeed,

$$\mu_{I,J}(p^#, q^#) = \mu_{I,J} \left( \sum_{u \in \ell_\text{p}[I]} u \otimes p \otimes \sum_{v \in \ell_\text{q}[J]} v \otimes q \right)$$

$$= \sum_{u \in \ell_\text{p}[I]} \sum_{v \in \ell_\text{q}[J]} \left( \sum_{w \in \text{Shuffle}(u,v)} w \otimes (p \times q) \right)$$

$$= \left( \sum_{u \in \ell_\text{p}[I]} \sum_{v \in \ell_\text{q}[J]} \sum_{w \in \text{Shuffle}(u,v)} w \right) \otimes (p \times q)$$

$$= \left( \sum_{w \in \ell_{p \times q}[I \sqcup J]} w \right) \otimes (p \times q)$$

$$= \mu_{I,J}(p, q)^#.$$ The second-to-last equality follows because every linear order on $I \sqcup J$ decomposes uniquely as a shuffle of a linear order in $I$ and a linear order in $J$, and because the product $p \times q$ is bounded in direction $w_{\text{rev}}$ if and only if $p$ and $q$ are bounded in directions $w_{\text{rev}}|_I$ and $w_{\text{rev}}|_J$ respectively.

Second, let $I, J$ be disjoint finite sets and $p \in \text{GP}_+[I \sqcup J]$. We must show that $\Delta^{\text{OGP}_+}(\text{Sym}(p)) = (\text{Sym} \otimes \text{Sym}) \circ \Delta_{I,J}(p)$. Indeed,
\[ \Delta_{I,J}^{\text{OGP}}(\text{Sym}(p)) = \Delta_{I,J} \left( \sum_{u \in \mathcal{L}_p[I \cup J]} w \otimes p \right) \]

\[ = \sum_{u \in \mathcal{L}_p[I \cup J], I \in \text{Init}(u)} (w|_I \otimes p|I) \otimes (w|_J \otimes p|/I) \]

\[ = \sum_{u \in \mathcal{L}_p[I]} \sum_{v \in \mathcal{L}_p[J]} (u \otimes p|I) \otimes (v \otimes p|/I) \]

\[ = (p|I)^\# \otimes (p|/I)^\# \]

\[ = (\text{Sym} \otimes \text{Sym}) \circ \Delta_{I,J}(p) \]

where the third equality follows from Lemma 4.4. \(\square\)

At this point we can write down a “symmetrized antipode” formula:

\[ \sum_{u \in \mathcal{L}_p[I]} s_I(w \otimes p) = s_I(p^\#) = s_I(p)^\# = (-1)^{|I|} \sum_{q \in \mathcal{L}_p[I]} (-1)^{\dim q}(u \otimes q). \quad (4.6) \]

The second equality arises because symmetrization is a Hopf morphism, hence commutes with the antipode, and the last equality follows from the Aguiar–Ardila formula (2.24) for the antipode in \(\text{GP}_+\). Note that the right-hand side of (4.6) is cancellation- and multiplicity-free. On the other hand, as we will see, the individual summands \(s(w \otimes p)\) can be extremely complicated.

**Remark 4.7.** Aguiar and Ardila [AA17, SS5.2–5.3] defined quotient monoids \(\text{GP}_+\) whose basis elements are equivalence classes of (extended) generalized permutohedra up to normal equivalence (i.e., equality of normal fans). All of our results, including the antipode formula to be proved in §7, are expressed in terms of normal fans, hence carry over mutatis mutandis to \(\text{L}^* \times \text{GP}_+\) and \(\text{L}^* \times \text{GP}_+\).

### 5. 0/1-EXTENDED GENERALIZED PERMUTOHEDRA

We next study the indicator complexes of possibly-unbounded 0/1-EGPs and show that they form a Hopf subclass of \(\text{OGP}_+\) that contains \(\text{OMat}\).

Define a vector subspecies \(\text{OIGP}_+ \subseteq \text{OGP}_+\) by

\[ \text{OIGP}_+[I] = \langle w \otimes p \in \text{OGP}_+[I] : p \text{ is a 0/1-EGP} \rangle. \]

Evidently \(\text{OIGP}_+\) is a Hopf submonoid of \(\text{OGP}_+\), because the 0/1-condition is clearly closed under taking products and faces. A bounded 0/1-EGP \(p\) is precisely a matroid base polytope [GGMS87, Thm. 4.1], and the indicator complex \(\Upsilon(p)\) is just the independence complex of the associated matroid, giving an injection \(\text{Mat} \to \text{OIGP}_+\). On the other hand, if \(p\) is unbounded, then \(\Upsilon(p)\) need not be a matroid complex, and some care is required in seeing how to derive \(\text{OIGP}_+\) from a Hopf class.
Example 5.1. The hypersimplex $\Delta_{2,4} \subset \mathbb{R}^4 = \mathbb{R}^4$ is the solution set of the following equation and inequalities:

\[
\begin{align*}
x_1 + x_2 + x_3 + x_4 &= 2 \\
x_1 &\leq 1 \\
x_2 &\leq 1 \\
x_3 &\leq 1 \\
x_4 &\leq 1 (**) \\
x_2 + x_3 + x_4 &\leq 2 \\
x_1 + x_2 + x_4 &\leq 2 \\
x_1 + x_2 + x_3 + x_4 &\leq 2 \\
x_1 + x_2 + x_3 &\leq 2
\end{align*}
\]

Dropping the two inequalities marked (**) produces the unbounded generalized permutohedron $p$ shown in Figure 3, with rays pointing in the direction $e_4 - e_1$. Let $w = 1234 \in \mathcal{G}_4$; then $w \in \ell_p[I]$ (specifically, $p_{w^{rev}} = 1100$) and so $(w, p) \in \text{OGP}_+$. Moreover, the indicator complex $\Upsilon(p) = \langle 12, 13, 23, 14 \rangle$ is prefix-pure with respect to $w$; we will see that this is not an accident. On the other hand, $\Upsilon(p)$ is not a matroid complex, since its restriction to $\{2, 3, 4\}$ is not pure. (One can see this geometrically as well: the convex hull of the vertices contains an edge between $(1, 0, 0, 1)$ and $(0, 1, 1, 0)$, which is not parallel to any vector $e_i - e_j$.)

![Figure 3](image_url)

Figure 3. An unbounded 0/1-EGP whose indicator complex is not a matroid.

Example 5.1 illustrates that indicator complexes of 0/1-EGPs form a nontrivial extension of the class of matroids. It would be of interest to find a purely combinatorial characterization of these complexes.

Theorem 5.2. The family of simplicial complexes

$$\text{OMAT}_+ = \{(w, \Upsilon(p), I) : p \subset \mathbb{R}^I \text{ is a 0/1-EGP with } w \in \ell_p[I]\}$$

is a Hopf class.

Proof. First we show that every element of $\text{OMAT}_+$ is prefix-pure. Let $(w, \Upsilon(p), I \sqcup J) \in \text{OMAT}_+$, where $I \in \text{Init}(w)$, and let $1_I$ be the linear functional defined by $1_I(x) = \sum_{i \in I} x_i$. Then $1_I \in \sigma_{I \sqcup J} \subseteq \sigma_{w^{rev}}$, so $1_I$ is bounded from above on $p$; in particular it is a face of $p$ containing $p_{w^{rev}}$. The complex $\Upsilon(p)|J$ is generated by the faces $\text{supp}(x) \cap J$ for all vertices $x \in p$, while $\Upsilon(p)|I$ is the pure subcomplex of $\Upsilon(p)|J$ generated by faces of maximum size (which correspond to vertices of $p$ maximized by $1_I$). Therefore, it suffices to show that $\Upsilon(p)|I = \Upsilon(p)|J$.
Accordingly, let \( \gamma = \text{supp}(x) \cap I \) be a face of \( \Upsilon(p)|I \). If \( x \) is not maximized by \( 1_I \), then \( p \) must contain some 1-dimensional face \( e \) incident to \( x \) such that walking along \( e \) from \( x \) increases the value of \( 1_I \). Since \( p \) is an EGP, this walk must be in the direction \( e_i - e_j \) for some \( i \in I \) and \( j \in J \), and \( 1_I \) is bounded from above on \( p \), so the walk must eventually reach another vertex \( y \in p \). But \( p \) is a 0/1-polyhedron, so it must be the case that \( x_i = y_j = 0 \) and \( x_j = y_j = 1 \), and \( \text{supp}(y) = \text{supp}(x) \cup \{i\}\{j\} \). Therefore \( \text{supp}(y) \cap I = \gamma \cup \{i\} \in \Upsilon(p)|I \). This argument shows that every facet of \( \Upsilon(p)|I \) is a face of \( \Upsilon(p|I) \), as required.

Closure under initial restriction and contraction follow from Lemma 4.4. For closure under ordered join, let \( (w_1, \Upsilon(p_1), I_1), (w_2, \Upsilon(p_2), I_2) \in \text{OMAT}_+ \). The faces of \( p_1 \times p_2 \) are products of faces of \( p_1 \) with faces of \( p_2 \), so

\[
w \in \ell_p[I_1 \sqcup I_2] \iff w|_{I_1} \in \ell_p[I_1] \quad \text{and} \quad w|_{I_2} \in \ell_p[I_2] \iff w \in \text{Shuffle}(w_1, w_2)
\]

and if these conditions hold then

\[
(w_1, \Upsilon(p_1)) \ast_w (w_2, \Upsilon(p_2)) = (w, \Upsilon(p_1) \ast \Upsilon(p_2)) = (w, \Upsilon(p_1 \times p_2)) \in \text{OMAT}_+
\]
as desired. \( \square \)

The Hopf monoid \( \text{OMAT}_+ = (\text{OMAT}_+)^2 \) (see §3.3) is therefore defined by

\[
\text{OMAT}_+[I] = \{ w \otimes \Upsilon(p) : w \otimes p \in \text{OIGP}_+[I] \}.
\]

Thus there is a surjective morphism of vector species \( \tilde{\Upsilon} = \text{Id} \otimes \Upsilon : \text{OIGP}_+ \to \text{OMAT}_+ \).

**Proposition 5.3.** The map \( \tilde{\Upsilon} : \text{OIGP}_+ \to \text{OMAT}_+ \) is a surjective Hopf morphism.

**Proof.** It is necessary to show that \( \tilde{\Upsilon} \) is compatible with shuffled join, initial restriction, and initial contraction. Compatibility with join follows from the observation that the vertices of \( p \times q \) are exactly concatenations of vertices of \( p \) with vertices of \( q \), and compatibility with initial restriction is just the identity \( \Upsilon(p|I) = \Upsilon(p)|I \) obtained in the proof of Theorem 5.2. For compatibility with initial restriction, let \( w \otimes p \in \text{OIGP}_+ \) and \( I \in \text{Init}(w) \); we must show that \( \Upsilon(p|I) = \Upsilon(p)/I \). Let \( \varphi \) be the \( w \)-lex-minimal facet of \( \Upsilon(p|I) = \Upsilon(p)/I \). Its characteristic vector \( e_{\varphi} \in \mathbb{R}^I \) is a vertex of \( p|I \), and by (2.8) the vertices of \( p/I \) are precisely

\[
\{ e_A \in \mathbb{R}^J \setminus I : A \subseteq J \setminus I, \; e_\varphi \times e_A \in p \}.
\]

But \( \varphi \) is also the \( w \)-lex-minimal facet of \( \Upsilon(p)|I \), so

\[
\Upsilon(p/I) = \{ A \subseteq J \setminus I : \varphi \cup A \in \Upsilon(p) \} = \text{link}_{\Upsilon(p)}(\varphi) = \Upsilon(p)/I
\]
as desired. \( \square \)

**Remark 5.4.** The map \( \tilde{\Upsilon} : \text{OIGP}_+ \to \text{OMAT}_+ \) is not injective. For example, let \( p, q \subset \mathbb{R}^2 \) as in Example 2.1, and let \( w = 21 \in \mathcal{S}_2 \). Then \( \sigma_w \in \mathcal{N}_q \) and so \( \tilde{\Upsilon}(w, p) = \tilde{\Upsilon}(w, q) \).

The relationships between the various Hopf monoids we have encountered are summarized in the following diagram.
The vector species \( \text{Mat}_+ \) is defined as the image of \( \text{OMat}_+ \) under the projection map \( \pi : L^* \times \text{GP} \to \text{GP} \); that is, it is the span of all indicator complexes of 0/1-EGPs. By Corollary 2.11, the dashed arrows are not Hopf morphisms; indeed, it seems unlikely that \( \text{Mat}_+ \) can be endowed with a Hopf monoid structure.

6. Antipodes of Facet-Initial and Shifted Complexes

Throughout this section, we fix a natural ordered prefix-pure complex \( (e, \Gamma, [n]) \) of dimension \( r - 1 \). Recall that \( E \) is the set composition \( 1|2|\cdots|n \) corresponding to \( e \).

For any interval \( J = [s, t] \), define the corresponding interval minor of \( (w, \Gamma, [n]) \) as \( (w|J, \Gamma(J), J) \), where \( \Gamma(J) = \Gamma(s, t) = (\Gamma|L \cup J)/L \) and \( L \) is the interval preceding \( J \). Moreover, for any natural set composition \( A = A_1|\cdots|A_k \models I \) (i.e., one whose blocks are intervals), define the reassembly of \( \Gamma \) with respect to \( A \) as \( \text{Re}_{A}(\Gamma) = \Gamma(A_1)*\cdots*\Gamma(A_k) \), so that

\[
\mu_A(\Delta_A(w \otimes \Gamma)) = \sum_{u \in \text{Shuffle}(w|A_1,\ldots,w|A_k)} (u \otimes \text{Re}_A(\Gamma)) = \sum_{u \in E_{p_1}, D(w,u) \leq A} (u \otimes \text{Re}_A(\Gamma)). \tag{6.1}
\]

Recall from (2.15) that \( \mu_A(\Delta_A(w \otimes \Gamma)) = 0 \) if \( A \) is not natural (i.e., if \( A \not\models E \)), so the Takeuchi formula (2.13) gives

\[
s(w \otimes \Gamma) = \sum_{A \leq W} (-1)^{|A|} \sum_{u \in \mathcal{S}_n, D(w,u) \leq A} u \otimes \text{Re}_A(\Gamma)
\]

\[
= \sum_{u \in \mathcal{S}_n} \sum_{A \models [n]} (-1)^{|A|} u \otimes \text{Re}_A(\Gamma)
\]

\[
= \sum_{u \in \mathcal{S}_n} \sum_{\text{reassemblies } \Omega \text{ of } \Gamma} \left( \sum_{A \in C^*_\Omega \cap E_{w,u}} (-1)^{|A|} \right) u \otimes \Omega \tag{6.2}
\]

where \( E_{w,u} \) is as defined in (2.20) and

\[
C^*_\Omega = \{ A \models [n] : A \leq E, \text{Re}_A(\Gamma) = \Omega \}. \tag{6.3}
\]

The album \( E_{w,u} \), which does not depend on \( \Gamma \), will appear later in our calculation of the antipode for \( \text{OGP}_+ \) (§7.2).
Further investigation of the antipode along these lines appears to require describing the album \( C_\Omega \), which may be quite complicated in general. Nevertheless, we make the following conjecture:

**Conjecture 6.1.** In every Hopf monoid arising from a Hopf class (equivalently, in \( \text{PRE}^3 \)), the antipode is multiplicity-free.

Equivalently, the “Euler characteristic” of the album \( C_\Omega \cap E_{w,u} \) defined in (6.3) is always 0 or ±1. We now present evidence in support of this conjecture, for a class of ordered complexes for which the albums \( C_\Omega \) can be described easily.

### 6.1. Facet-initial complexes.

**Definition 6.2.** Let \((w, \Gamma, [n])\) be an ordered prefix-pure complex, and let \( r = \dim \Gamma + 1 \). We say that \((w, \Gamma)\) is **facet-initial** if either \( \Gamma = \{\emptyset\} \), or if \([r]\) is a facet of \( \Gamma \) (hence the lex-minimal facet).

Adapting terminology from matroid theory, we say that a vertex of \( \Gamma \) is a **coloop** if it belongs to every facet, and a **loop** if it belongs to no facet (hence to no face); in addition, we say that \( \Gamma \) is **primitive** if it has no loops or coloops. The facet-initial property is (much) more general than shiftedness, and is preserved by restriction and contraction, hence by taking interval minors (though not by join). The interval minors of \( \Gamma \) are

\[
\Gamma(s, t) = \{ \gamma \subseteq [s, t] : \gamma \cup [1, s - 1] \in \Gamma \}. \tag{6.4}
\]

In particular, \( \Gamma(s, t) \) is a simplex if \( t \leq r \) and is empty if \( s > r \). Therefore, for any natural set composition \( A = A_1 | \cdots | A_k \vdash I \) (i.e., one whose blocks are intervals), suppose that \( A_j = [s, t] \) is the block of \( A \) containing \( r \) (so \( 1 \leq s \leq r \leq t \leq n \)). Then the reassembly \( \text{Re}_A(\Gamma) \) that occurs in (6.1) is

\[
\Gamma^*(s, t) := \langle [1, s - 1] \rangle \ast \Gamma(s, t);
\]

in particular \( \text{Re}_A(\Gamma) \) and the albums \( C_\Omega \) of (6.3) depend only on the interval \([s, t]\).

**Theorem 6.3.** Let \((w, \Gamma, [n])\) be a facet-initial ordered simplicial complex. Then:

1. Its antipode is given by the formula
   \[
   s(w \otimes \Gamma) = \sum_{s=1}^{r} \sum_{t=r}^{n} (-1)^{n-1-t+s} \sum_{u \in \text{Sh}(s, t)} u \otimes \Gamma^*(s, t) \tag{6.5}
   \]
   where \( \text{Sh}(s, t) = \text{Shuffle}([s-1, s-2, \ldots, 1], [s, \ldots, t], [n, n-1, \ldots, t+1]) \subseteq \mathfrak{S}_n \).

2. If in addition \( \Gamma \) is shifted and has no loops or coloops, then the formula is cancellation-free.

We will establish the formula immediately, but defer the proof of the second statement until we focus on shifted complexes in the next section.

**Proof of Theorem 6.3 (1).** By the foregoing observations about facet-initial complexes, we can rewrite (6.2) as

\[
s(w \otimes \Gamma) = \sum_{s=1}^{r} \sum_{t=r}^{n} \sum_{A : [n] \text{ natural:}} (-1)^{|A|} \sum_{u \in \mathfrak{S}_n : D(w, u) \subseteq A} u \otimes \Gamma^*(s, t). \tag{6.6}
\]
Observe that if \([s, t] \in \mathcal{A}\) and \(D(w, u) \subseteq \mathcal{A}\) then \(u^{-1}(s) < \cdots < u^{-1}(t)\). Moreover, for fixed \(s\) and \(t\) and a permutation \(u\) obeying this last condition, any natural set composition \(\mathcal{A}\) containing \([s, t]\) as a block satisfies \(D(w, u) \subseteq \mathcal{A}\) if and only if \(B \subseteq \mathcal{A} \subseteq C\), where

\[
\begin{align*}
B &= B_{r,s,t} = \left([1, s-1], [s,t], [t+1,n]\right) \lor D(w, u), \\
C &= C_{r,s,t} = 1 \mid \cdots \mid s-1 \mid [s,t] \mid t+1 \mid \cdots \mid n
\end{align*}
\]

(here \(\lor\) denotes the join in the lattice of natural set compositions). Therefore, we may rewrite the right-hand side of (6.6) as

\[
\sum_{s=1}^{r} \sum_{t=r}^{n} \sum_{u \in \mathfrak{S}_{n}} \left( \sum_{B \subseteq \mathcal{A} \subseteq C} (-1)^{|A|} \right) u \otimes \Gamma^*(s, t). \tag{6.7}
\]

The parenthesized sum, over a Boolean interval, vanishes unless \(B = C\). In this case the sum equals \((-1)^{n-1 -(t-s)}\), and since \(1, \ldots, s-1\) and \(t+1, \ldots, n\) are singleton parts in \(D(w, u)\) it follows that

\[
\begin{align*}
u^{-1}(1) &> \cdots > u^{-1}(s-1), \\
u^{-1}(s) &< \cdots < u^{-1}(t), \\
u^{-1}(t+1) &> \cdots > u^{-1}(n).
\end{align*} \tag{6.8}
\]

(These conditions, together with \(u^{-1}(s) < \cdots < u^{-1}(t)\), say precisely that \(u \in \text{Sh}(s, t)\), yielding the desired formula. \(\square\)

The formula of Theorem 6.3 is not cancellation-free in all cases, because there can exist \(s, t, s', t'\) such that \(\Gamma^*(s, t) = \Gamma^*(s', t')\) and \(\text{Sh}(s, t) \cap \text{Sh}(s', t')\) is nonempty. However, this possibility is limited, and in fact we can track the cancellation exactly. Say that a permutation \(u \in \mathfrak{S}_{n}\) is \textbf{DUD} (for \textit{down-up-down}) if it satisfies the inequalities

\[
\begin{align*}
u^{-1}(1) &> \cdots > u^{-1}(S), \\
u^{-1}(S) &< \cdots < u^{-1}(T), \\
u^{-1}(T) &> \cdots > u^{-1}(n)
\end{align*}
\]

where \(S = S(u), \ldots, r, \ldots, T = T(u)\) is the maximal increasing subsequence of \(u\) containing \(r\) (in particular, \(S \leq r \leq T\)). Observe that \(u \in \text{Sh}(s, t)\) if and only if it is DUD, with \(s \in \{S, S+1\}\) and \(t \in \{T, T-1\}\), or equivalently,

\[
s-1 \leq S \leq s \leq r \leq t \leq T \leq t+1.
\]

Thus we can regroup the formula of Theorem 6.3 by summing over permutations, always remembering that \(S\) and \(T\) depend on \(u\):
\[
s(w \otimes \Gamma) = \sum_{u \in DUD, S < r < T} (-1)^{n-T+S-1} u \otimes \left( \Gamma^*(S, T) - \Gamma^*(S, T - 1) - \Gamma^*(S + 1, T) + \Gamma^*(S + 1, T - 1) \right) \\
+ \sum_{u \in DUD, S = r = T} (-1)^{n-r+S-1} u \otimes \left( \Gamma^*(S, r) - \Gamma^*(S + 1, r) \right) \\
+ \sum_{u \in DUD, S = r = T} (-1)^{n-T+r-1} u \otimes \left( \Gamma^*(r, T) - \Gamma^*(r, T - 1) \right) \\
+ \sum_{u \in DUD, S = r = T} (-1)^{n-T+S-1} u \otimes \Gamma^*(S, T)
\]

(6.9)

By definition, \( \Gamma^*(s, r) = \langle [1, r] \rangle \) for every \( s \leq r \), so the second sum in (6.9) vanishes. Cancellation in the third sum is easy to track: \( \Gamma^*(r, T) \) is generated by the facets of \( \Gamma \) of the form \([r - 1] \cup \{x\} \) with \( r \leq x \leq T \), so the third summand is nonzero if and only if \([r - 1] \cup \{T\} \in \Gamma \).

We now consider cancellation in the first sum. The relevant conditions are

(a) \( T \) is a loop in \( \Gamma(S, T) \);
(b) \( T \) is a loop in \( \Gamma(S + 1, T) \);
(c) \( S \) is a coloop in \( \Gamma(S, T) \);
(d) \( S \) is a coloop in \( \Gamma(S, T - 1) \).

The conditions for equality between each pair are indicated in the following diagram:

\[
\begin{align*}
\Gamma^*(S, T) &= \langle [1, S - 1] \rangle \ast \Gamma(S, T) \\
\Gamma^*(S + 1, T) &= \langle [1, S] \rangle \ast \Gamma(S + 1, T) \\
\Gamma^*(S, T - 1) &= \langle [1, S - 1] \rangle \ast \Gamma(S, T - 1) \\
\Gamma^*(S + 1, T - 1) &= \langle [1, S] \rangle \ast \Gamma(S + 1, T - 1)
\end{align*}
\]

(6.10)

Note that (a) \( \Rightarrow \) (b) and (c) \( \Rightarrow \) (d). Moreover, by the diagram above, it is not possible that exactly three of the conditions are true. The remaining logical possibilities, and the resulting cancellation in the summand, are given by the following table.

<table>
<thead>
<tr>
<th>True</th>
<th>False</th>
<th>Simplified form</th>
</tr>
</thead>
<tbody>
<tr>
<td>a,b,c,d</td>
<td>—</td>
<td>0</td>
</tr>
<tr>
<td>a,b</td>
<td>c,d</td>
<td>0</td>
</tr>
<tr>
<td>c,d</td>
<td>a,b</td>
<td>0</td>
</tr>
<tr>
<td>b,d</td>
<td>a,c</td>
<td>( \Gamma^<em>(S, T) - \Gamma^</em>(S, T - 1) ) or ( \Gamma^<em>(S, T) - \Gamma^</em>(S + 1, T) )</td>
</tr>
<tr>
<td>b</td>
<td>a,c,d</td>
<td>( \Gamma^<em>(S, T) - \Gamma^</em>(S, T - 1) )</td>
</tr>
<tr>
<td>d</td>
<td>a,b,c</td>
<td>( \Gamma^<em>(S, T) - \Gamma^</em>(S + 1, T) )</td>
</tr>
<tr>
<td>—</td>
<td>a,b,c,d</td>
<td>( \Gamma^<em>(S, T) - \Gamma^</em>(S, T - 1) - \Gamma^<em>(S + 1, T) + \Gamma^</em>(S + 1, T - 1) )</td>
</tr>
</tbody>
</table>
Putting these observations together leads to the following formula (which is cancellation-free and multiplicity-free) for the antipode of a facet-initial complex:

\[
\begin{align*}
s(w \otimes \Gamma) &= \sum_{u \in \mathcal{U} \cup \mathcal{D}} (-1)^{n-T+S-1} u \otimes (\Gamma^*(S, T) - \Gamma^*(S, T - 1) - \Gamma^*(S + 1, T) + \Gamma^*(S + 1, T - 1)) \\
&\quad + \sum_{u \in \mathcal{U} \cup \mathcal{D}} (-1)^{n-T+S-1} u \otimes (\Gamma^*(S, T) - \Gamma^*(S + 1, T)) \\
&\quad + \sum_{u \in \mathcal{U} \cup \mathcal{D}} (-1)^{n-T+S-1} u \otimes (\Gamma^*(r, T) - \Gamma^*(r, T - 1)) \\
&\quad + \sum_{u \in \mathcal{U} \cup \mathcal{D}} (-1)^{n-1} u \otimes \langle [1, r] \rangle.
\end{align*}
\]

(6.11)

Here we have combined the fourth and fifth cases in the table. Alternatively, it is possible to combine the fourth and sixth cases and write a similar formula, which we omit.

6.2. **Shifted complexes.** We now consider the case of a pure ordered complex \((w, \Gamma, [n])\) that is not merely facet-initial but in fact **shifted**; i.e., its facets form an order ideal in Gale order (see Example 3.7). We write \(\langle \varphi_1, \ldots, \varphi_m \rangle_I\) for the shifted matroid on vertex set \(I\) whose facets are the Gale order ideal generated by the \(\varphi_i\); for example, \(\langle 14, 23 \rangle_{[4]} = \langle 12, 13, 14, 23 \rangle\). Note that the coloops of \(\Gamma\) form an initial segment \([1, a]\) and its loops form a final segment \([z, n]\), where \(a \leq r < z\). The definitions of loop and coloop imply that

\[
[1, r + 1]\{x\} \in \Gamma \iff x > a
\]

(6.12a)

and

\[
[1, r - 1]\{x\} \in \Gamma \iff x < z.
\]

(6.12b)

In particular, \(\Gamma\) is coloop-free if and only if \([2, r + 1]\) is a facet, and is loop-free if and only if \([1, r - 1] \cup \{n\}\) is a facet. (If \(\Gamma\) has no coloops we may set \(a = 0\), and if it has no loops then \(z = n + 1\).)

**Lemma 6.4.** Let \((w, \Gamma)\) be a pure shifted complex of dimension \(r - 1\) on vertex set \([1, n]\) with \(w = e\) the natural ordering. Suppose that the coloops of \(\Gamma\) are \([1, a]\) and the loops are \([z, n]\). (Note that \(a \leq r < z\).) Let \([s, t] \subseteq [1, n]\) be an interval such that \(s \leq r \leq t\). Then:

1. If \(t = r\), then \(\Gamma(s, t) = \langle [s, t] \rangle\) and so \(\Gamma^*(s, t) = \langle [1, r] \rangle\).
2. If \(t > r\), then the coloops of \(\Gamma(s, t)\) are \([1, a] \cap [s, t]\) and the loops are \([z, n] \cap [s, t]\). Thus

\[
\Gamma(s, t) = \langle [1, a] \cap [s, t] \rangle \ast \Gamma(a + 1, \min(t, z - 1))
\]

and so

\[
\Gamma^*(s, t) = \langle [1, s - 1] \rangle \ast \langle [1, a] \cap [s, t] \rangle \ast \Gamma(a + 1, \min(t, z - 1))
\]

\[= \langle [1, \max(s - 1, a)] \rangle \ast \Gamma(a + 1, \min(t, z - 1))\]
and moreover \( \Gamma(a+1, \min(t, z-1)) \) is primitive.

Proof. The first assertion is immediate from (6.4). Henceforth, suppose that \( t > r \). Let \( x \in [s, t] \). Then by (6.4) and (6.12a)

\[
[s, r+1] \setminus \{x\} \in \Gamma(s, t) \iff [1, r+1] \setminus \{x\} \in \Gamma \iff x > a
\]

and by (6.4) and (6.12b)

\[
[s, r-1] \cup \{x\} \in \Gamma(s, t) \iff [1, r-1] \setminus \{x\} \in \Gamma \iff x < z
\]

from which the statement about loops and coloops follows, and the rest is calculation. \(\square\)

In the third case \( s \leq r < t \), note that if \( \Gamma \) is primitive then so is \( \Gamma(s, t) \). Moreover, \( \Gamma(s, t) \)
cannot be a simplex (because \( a < t \)) or empty (because \( s < z \)).

**Corollary 6.5.** \( \Gamma^*(s, t) = \Gamma^*(s', t') \) if and only if

(i) \( t = t' = r \); or

(ii) \( t, t' > r, \min(t, z-1) = \min(t', z-1), \) and \( \max(s-1, a) = \max(s'-1, a) \).

Equivalently: (i) \( t = t' = r \); or (ii) either \( r < t = t' < z \) or \( t, t' \geq z \), and either \( s, s' \leq a + 1 \) or \( s = s' > a + 1 \).

We can now revisit the cancellation-free formula (6.11). The conditions (a) . . . (d) now become

- (a) \( T \) is a loop in \( \Gamma(S, T) \) \iff \( T \geq z \).
- (b) \( T \) is a loop in \( \Gamma(S+1, T) \) \iff \( T \geq z \).
- (c) \( S \) is a coloop in \( \Gamma(S, T) \) \iff \( T = r \), or \( T > r \) and \( S \leq a \).
- (d) \( S \) is a coloop in \( \Gamma(S, T-1) \) \iff \( T = r \), or \( T = r+1 \), or \( T > r+1 \) and \( S \leq a \).

In the first sum, to say that (a) . . . (d) all fail is to say that \( r + 1 < T < z \) and \( S > a \). The second sum disappears because conditions (a) and (b) are equivalent for shifted complexes. In the third sum, to say that (a), (b), (c) all fail but (d) holds is to say that \( T = r+1 \) and \( S > a \). In the fourth sum, the condition \( [r-1] \cup \{T\} \) becomes \( T < z \) by (6.12b). Thus we can simplify (6.11) slightly to the cancellation-free formula

\[
s(w \otimes \Gamma) = \sum_{u \in \mathcal{D}, u < S < r} (-1)^{n-T+S-1} u \otimes (\Gamma^*(S, T) - \Gamma^*(S, T-1) - \Gamma^*(S+1, T) + \Gamma^*(S+1, T-1))
\]

\[
+ \sum_{u \in \mathcal{D}, u < S < r, T = r+1 < z} (-1)^{n-r+S} u \otimes (\Gamma^*(S, r+1) - \Gamma^*(S+1, r+1))
\]

\[
+ \sum_{u \in \mathcal{D}, S = r < T < z} (-1)^{n-T+r-1} u \otimes (\Gamma^*(r, T) - \Gamma^*(r, T-1))
\]

\[
+ \sum_{u \in \mathcal{D}, S = r = T} (-1)^{n-1} u \otimes \langle 1, r \rangle.
\]

(6.13)

We can now complete the proof of Theorem 6.3.

**Proof of Theorem 6.3 (2).** Let \( (w, \Gamma, I) \) be a shifted complex with no loops or coloops. By Lemma 6.4, all complexes \( \Gamma(s, t) \) with \( s \leq r \leq t \) are also loopless and coloopless. For each complex \( \Gamma^*(s, t) \) we can recover \( s \) and \( t \) from the coloops and the loops respectively. It follows that formula (6.5) is cancellation-free. \(\square\)

38
Remark 6.6. The simplicial complexes $\Gamma^*(s, t)$ are shifted with respect to $e$ (by virtue of being minors of the shifted complex $\Gamma$) but not necessarily with respect to the permutations $u$ with which they are paired in the formula of Theorem 6.3. (We should not expect them to be so, since ordered shifted complexes do not form a Hopf class or a Hopf monoid; see Example 3.7.)

Observe that the indexing of the terms in the antipode formula given by (6.13) depends only on the parameters $r, n, a, z$; this will be useful shortly.

6.3. Shifted (Schubert) matroids. Klivans [Kli03, Thm. 5.4.1] proved that a shifted complex is a matroid independence complex if and only if it is a principal ideal in Gale order. These complexes also appear in the literature under the name Schubert matroids.

Let $\varphi = \{a_1 < \cdots < a_r\} \subseteq [n]$. We can represent the shifted matroid $\langle \varphi \rangle_{[n]}$ as the Ferrers diagram of the partition $(a_1 - 1, \ldots, a_r - r)$ (here it is convenient to write partitions in weakly increasing order). This correspondence gives an isomorphism between Gale order on $r$-subsets of $[n]$ and the interval in Young’s lattice from the empty partition to the rectangle $r \times (n - r)$ with $r$ rows and $n - r$ columns. In particular, Gale order is a (distributive) lattice whose join and meet correspond respectively to union and intersection of Ferrers diagrams. If we label rows $1, \ldots, r$ south to north and columns $r + 1, \ldots, n$ west to east, then empty rows at the south are coloops and empty columns on the east are loops. For $s \leq r < t$, the complexes $\Gamma(s, t)$ and $\Gamma^*(s, t)$ are obtained by erasing all rows south of $s$ and all columns east of $t$ and regarding the result as a subdiagram of $[s, r] \times [r + 1, t]$ or of $[1, r] \times [r + 1, n]$ respectively. This observation is the pictorial version of the formula

$$\langle \varphi \rangle_{[n]}(s, t) = \langle \varphi' \wedge [t - r + s, t] \rangle_{[s, t]},$$

(6.14)

where $\varphi' = \{a_s, \ldots, a_r\}$ and $\wedge$ denotes meet in Gale order (we omit the routine verification). Thus the class of shifted matroids is closed under taking interval minors.

For example, the shifted matroid $\langle 23589 \rangle_{[11]}$ (with $r = 5$) corresponds to the Ferrers diagram of the partition $(4, 4, 2, 1, 1) = (9 - 5, 8 - 4, 5 - 3, 3 - 2, 2 - 1)$, considered as a subset of a $r \times (n - r) = 5 \times 6$ rectangle (see Figure 4).

\[\begin{array}{cccccc}
6 & 7 & 8 & 9 & 10 & 11 \\
5 & & & & & \\
4 & & & & & \\
3 & & & & & \\
2 & & & & & \\
1 & & & & & \\
\end{array}\]

\[\begin{array}{cccccc}
6 & 7 & 8 & 9 & 10 & 11 \\
5 & & & & & \\
4 & & & & & \\
3 & & & & & \\
2 & & & & & \\
1 & & & & & \\
\end{array}\]

$\Gamma = \langle 23589 \rangle_{[11]}$

\[\begin{array}{cccccc}
5 & & & & & \\
4 & & & & & \\
3 & & & & & \\
2 & & & & & \\
1 & & & & & \\
\end{array}\]

$\Gamma(2, 8)$

**Figure 4.** A shifted matroid and an interval minor, represented as Ferrers diagrams.

Meanwhile, let us interpret reassemblies of the shifted matroid $\Gamma$ geometrically. Let $\mathfrak{p}$ be the matroid polytope of $\Gamma$ (equivalently, its indicator polytope; see §2.1). For every
natural set composition $A = A_1 | \cdots | A_k \models I$, iterating (2.8) gives
\[ p_A = p_{A_1} \times \cdots \times p_{A_k} \]
where $p_{A_i}$ is the matroid polytope of the interval minor $\Gamma(A_i)$. Thus the indicator complex of $p_A$ is precisely the reassembly $\text{Re}_A(\Gamma)$.

Let $\Phi \subseteq \Gamma$ be shifted complexes on $[n]$ with the same parameters $r, n, a, z$ of the same dimension, and let $1 \leq s \leq t \leq n$. Thus, as mentioned above, the terms in the expressions for $s(w \otimes \Phi)$ and $s(w \otimes \Gamma)$ given by (6.13) are indexed identically. Moreover, an easy calculation shows that
\[ \Gamma(s, t) \cap \Phi = \Phi(s, t) \quad \text{and so} \quad \Gamma^*(s, t) \cap \Phi = \Phi^*(s, t). \quad (6.15) \]

As a result, we can interpret the cancellation-free antipode formula (6.13) of any shifted complex $\Phi$ quasi-geometrically by taking $\Gamma$ to be any shifted matroid containing $\Phi$, so that the terms $u \otimes \Phi^*(s, t)$ in (6.13) correspond bijectively to the faces of the base polytope of $\Gamma$. For example, $\Gamma$ could be taken to be the matroid hull of $\Phi$ (the unique smallest shifted matroid containing $\Phi$, generated by the Gale join of all its facets).

7. THE ANTIPODE IN OGP

The goal of this section is to establish an antipode formula for the Hopf monoid OGP, and thus for its submonoids OGP and OMat. The argument is modeled after Aguiar and Ardila’s topological calculation of the antipode in GP [AA17, Theorem 7.1]. It works in general for OGP. The computations rely heavily on the normal fan of the polyhedron and the fact that it is (topologically) closed even for unbounded polyhedra. This implies that the closure of the normal cone of a face still makes sense in constructing objects such as $E$ and $F$ below.

7.1. Scrope complexes. We begin by describing a class of simplicial complexes that will play a key role in the computation of the antipode on OGP.

**Definition 7.1.** A Scrope complex is a simplicial complex on vertices $[k - 1]$ that is either a simplex, or is generated by faces of the form $[k - 1] \setminus [x, y - 1] = [1, x - 1] \cup [y, k - 1]$, where $1 \leq x < y \leq k$. If $z = ((x_1, y_1), \ldots, (x_r, y_r))$ is a list of ordered pairs of integers in $[k]$ with $x_i < y_i$ for each $i$, we set $\varphi_i = [k - 1] \setminus [x_i, y_i - 1]$ for $1 \leq i \leq r$ and define
\[ \text{Scr}(k, z) = \langle \varphi_1, \ldots, \varphi_r \rangle. \]

The facets of a Scrope complex correspond to the intervals $[x, y - 1]$ that are minimal with respect to inclusion. By removing redundant generators, we may assume that it is either the full simplex on $[k - 1]$, or can be written as $\text{Scr}(k, z)$ where $1 \leq x_1 < \cdots < x_r < k$; $1 < y_1 < \cdots < y_r \leq k$; and $x_i < y_i$ for each $i$.

To justify the above notational choices, we will be considering Scrope complexes whose vertices correspond to the $k - 1$ separators in a natural set composition of $\{1, 2, \ldots, k\}$. Thus $[k - 1] \setminus [x, y - 1]$ is the set of separators in the set composition whose only non-singleton block is $\{x, x + 1, \ldots, y - 1, y\}$, namely
\[ 1 \mid 2 \mid \cdots \mid x \mid x + 1 \mid \cdots \mid y - 1 \mid y \mid y + 1 \mid \cdots \mid k. \]

\[ 7 \text{Named after the winner of an important 1389 case in English heraldry law, concerning a coat of arms that looks a lot like the dots-and-stars diagram.} \]
A Scrope complex can be recognized by its facet-vertex incidence matrix, which we will represent as a \( r \times (k-1) \) table whose \((i,j)\) entry is \( \ast \) or \( \cdot \) according as \( j \in \varphi_i \) or \( j \notin \varphi_i \). Thus each row consists of a (possibly empty) sequence of dots sandwiched between two (possibly empty) sequences of stars. For example, if \( k = 7 \) and \( z = (1, 3), (2, 4), (3, 6), (4, 7) \) then \( \text{Scr}(n, z) = \langle 3456, 1456, 126, 123 \rangle \) is represented by the following diagram:

\[
\begin{array}{cccccc}
\cdot & \cdot & \ast & \ast & \ast & \ast \\
\cdot & \cdot & \ast & \ast & \ast & \ast \\
\ast & \ast & \cdot & \cdot & \cdot & \ast \\
\ast & \ast & \ast & \cdot & \cdot & \cdot \\
\end{array}
\]

It is easy to see from this description that the class of Scrope complexes is stable under taking induced subcomplexes.

**Proposition 7.2.** Every nontrivial Scrope complex is either contractible or a homotopy sphere.

**Proof.** Let \( \Gamma = \langle \varphi_1, \ldots, \varphi_r \rangle \) be a Scrope complex, labeled as above. One trivial case is that \( r = 1, x_1 = 1, \) and \( y_1 = k \), which we allow for inductive purposes. In this case \( \Gamma \) is the trivial complex, which we regard as the \((-1)-sphere\). Otherwise, if \( r = 1 \), then \( \Gamma \) is a simplex, hence contractible. Also, if \( y_r < k \), then each facet contains vertex \( k - 1 \), so \( \Gamma \) is again contractible. Therefore, suppose that \( r > 1 \) and \( y_r = k \), so that \( \varphi_r = [1, x_r - 1] \).

Let \( \hat{\Gamma} = \langle \varphi_1, \ldots, \varphi_{r-1} \rangle \). This complex is certainly a cone with apex \( k - 1 \), hence contractible. Now \( \Gamma \) is the union of the contractible complexes \( \hat{\Gamma} \) and \( \langle \varphi_r \rangle \), attached along their intersection \( \Gamma' \), namely

\[
\langle \varphi_r \rangle \cap \hat{\Gamma} = \langle \varphi_r \cap \varphi_i : 1 \leq i \leq r - 1 \rangle \\
= \langle [1, x_r - 1] \cap ([1, x_i - 1] \cup [y_i, n - 1]) : 1 \leq i \leq r - 1 \rangle \\
= \langle [1, x_i - 1] \cup [y_i, \min(x_r - 1, n - 1)] : 1 \leq i \leq r - 1 \rangle
\]

which is evidently itself a (possibly trivial) Scrope complex. By induction, either \( \Gamma' \) is contractible, which implies that \( \Gamma \) is contractible as well, or else \( \Gamma' \simeq \mathbb{S}^q \) for some \( q \), which implies \( \Gamma \simeq \mathbb{S}^{q+1} \). \( \square \)

**Corollary 7.3.** The reduced Euler characteristic of every Scrope complex is 0, 1, or \(-1\).

As a corollary of the proof, the reduced Euler characteristic of a Scrope complex can be computed recursively, with computation time linear in the number of generators \( r = |z| \).

### 7.2. The antipode calculation

Throughout this section, \( I \) will denote a set of size \( n \) and \( w, u \) linear orders on \( I \). Let \( W \) be the maximal set composition corresponding to \( w \), and let \( D = D(w, u) \) be the \( u \)-descent composition of \( w \) (Definition 2.9). Define fans and albums as follows:

\[
\mathcal{E} = \mathcal{E}_{w,u} = \{ \sigma_A \in \overline{C_w} : D \leq A \}, \quad \mathcal{E} = \mathcal{E}_{w,u} = \{ A : \sigma_A \in \mathcal{E} \} = \{ A : D \leq A \leq W \},
\]

\[
\mathcal{F} = \mathcal{F}_{w,u} = \{ \sigma_A \in \overline{C_w} : D \nleq A \}, \quad \mathcal{F} = \mathcal{F}_{w,u} = \{ A : \sigma_A \in \mathcal{F} \} = \{ A : D \nleq A, A \leq W \}
\]

(we repeat the definition of \( \mathcal{E} \) from (2.20)).

The topological realization of the Boolean algebra \( C_W \) is the \((n-2)\)-simplex \( \tilde{\mathcal{C}}_w = \Sigma^{n-2} \cap \mathcal{C}_w = \langle \tilde{\sigma}_w \rangle \). The descent composition \( D = D(w, u) \) corresponds to the face \( \delta = \tilde{C}_D \) of this
simplex, and $F$ corresponds to the closed subcomplex $\tilde{F}_{w,u} \subseteq \langle \delta_w \rangle$ consisting of faces not containing $\delta$. In particular,

$$\tilde{F}_{w,u} \approx \begin{cases} \emptyset & \text{if } |D| = 1 \iff u = w, \\ \mathbb{B}^{n-3} & \text{if } 1 < |D| < n, \\ \mathbb{S}^{n-3} & \text{if } |D| = n \iff u = w^{\text{rev}}. \end{cases}$$

In fact we can say more about the structure of $\tilde{F}$: it is obtained by coning the boundary of the simplex $\langle \delta \rangle$ successively with each vertex in $\sigma_w \setminus \delta$. It is worth mentioning that if $\tilde{F}$ is nonempty then it is a very special kind of shellable complex: a pure full-dimensional simplex, and

$\operatorname{OGP}$ be a basis element of $\mathcal{F}$.

A corollary of Proposition 7.4 (Locality of antipode in $\mathcal{OGP}_+$). Suppose that $a^{w,p}_{u,q} \neq 0$. Then

$$C_w \cap C_q^\circ \neq \emptyset \quad \text{or equivalently} \quad C_w \cap C_q^\circ \neq \emptyset; \quad \text{and} \quad (\star)$$

$$\sigma_D \in C_q \quad \text{or equivalently} \quad D \in C_q. \quad (\star\star)$$

Proof. First, $E \subseteq C_W$, so if $(\star)$ fails then the sum in (7.1) is empty. (In fact, $(\star)$ follows from the third line of the calculation of $s(w \otimes p)$ above.) If $(\star\star)$ fails, then $E \cap C_q = \emptyset$ (since $C_q$ is closed under coarsening), whence $E \subseteq C_q^\circ = \emptyset$ and the sum in (7.1) is again empty.

Corollary 7.5. If $a^{w,p}_{u,q} \neq 0$, then $Q$ is $w$-natural.

42
Proof. Let \( x <_Q y \) be a relation and \( A \) a set composition such that \( A \subseteq C_W \cap C_Q \). By Lemma 2.5, \( x, y \) are in different blocks of \( A \), and by \( w \)-naturality of \( A \) we have \( w^{-1}(x) < w^{-1}(y) \). Therefore \( Q \) is \( w \)-natural. \( \square \)

Proposition 7.4 says that the support of \( s^{O GP}(w \otimes p) \) is local with respect to the braid cone \( \sigma_w \). Condition (*) is stronger than the property that the face \( q \) associated to the preposet \( Q \) must contain the vertex \( p_w \): A face can contain the vertex \( p_w \) without Condition (*), as in Example 7.8.

**Remark 7.6.** By Definition 2.4 for any \( d \)-dimensional GP \( p \) there is a map \( \psi \) from the set of faces of \( p \) to the set of faces of \( \Pi_{d+1} \). This map can be thought as a deformation map, a face \( q \) maps to the set of faces of \( \Pi_{d+1} \) that came together. Locality for \( \Pi_{d+1} \) means that the support of the antipode is exactly equal to the star of the vertex \( w \). Locality for \( p \) means that the support of the antipode is equal to the faces \( q \subseteq p \) such that \( \psi(q) \cap \text{star}(w) \neq \emptyset \).

**Remark 7.7.** By contrast, the antipode in \( L \otimes GP \) (as opposed to \( L^{*} \otimes GP \)) is not local. For example, let \( p \subseteq \mathbb{R}^n \) be the standard permutohedron, whose normal fan is the braid fan \( B_n \). In particular, if \( A \in \text{Comp}(n) \), then \( \mu_A \circ \Delta_A(p) = p_A \) is the unique face of \( p \) with normal cone \( \sigma_A \subseteq B_n \). Thus

\[
 s^{L \otimes GP}(w \otimes p) = \sum_{A=[n]} \mu_A^L(\Delta_A^L(w)) \otimes p_A.
\]

Here each term in the sum is an element of the canonical basis of \( L \otimes GP[I] \) and the second part of the tensor is different for all terms. Thus all faces of \( p \) appear in the antipode, and we see that the algebraic structure of \( L \times GP \) is not local.

**Example 7.8.** Let \( w = 1234 \in \mathfrak{S}_4 \), and let \( p \) be the hypersimplex \( \Delta_{2,4} \) (see §8.3), which is an octahedron with vertices 0011, 0101, 0110, 1001, 1010, 1100 \( \in \mathbb{R}^4 \) (abbreviating, e.g., 0011 = \((0, 0, 1, 1)\)). By the characterization of faces of hypersimplices (Prop. 8.3), the only faces of \( p \) that occur in the support of \( s(w \otimes p) \) are as indicated in Figure 5.

![Figure 5: Locality for the hypersimplex \( \Delta_{2,4} \).](image-url)
For the purpose of calculating $a_{u,q}^{w,p}$, we assume from now on that conditions (⋆) and (⋆⋆) hold for the pair $u, q$. We start by rewriting $a_{u,q}^{w,p}$ as a sum of “reduced Euler characteristics” over fans:

$$a_{u,q}^{w,p} = \chi_1 - \chi_2 - \chi_3,$$

where

$$\chi_1 = \sum_{\sigma \in C_w \cap C_q} (-1)^{\dim \sigma} = \sum_{A \in C_W \cap C_Q} (-1)^{|A|},$$

$$\chi_2 = \sum_{\sigma \in F \cap C_q} (-1)^{\dim \sigma} = \sum_{A \in F \cap C_Q} (-1)^{|A|},$$

$$\chi_3 = \sum_{\sigma \in E \cap C_q} (-1)^{\dim \sigma} = \sum_{A \in E \cap C_Q} (-1)^{|A|}.$$

In light of the argument of [AA17, Theorem 7.1], one might expect our calculation of $a_{u,q}^{w,p}$ to proceed by expressing $E \cap C_q = (C_w \setminus F) \cap (C_q \setminus C_q)$ as a signed sum of the four closed fans $C_w \cap C_q, F \cap C_q, C_w \cap \partial C_q, F \cap \partial C_q$. As it happens, it is difficult to determine the reduced Euler characteristics of the last two of these fans, but it is feasible (via the theory of Scrope complexes, as we will see) to analyze the single (non-closed) fan $E \cap \partial C_q$.

We will now calculate each of $\chi_1, \chi_2,$ and $\chi_3$ separately, working either geometrically or combinatorially as convenient and assuming in each case that the conditions of Proposition 7.4 hold.

**Proposition 7.9.** Under the locality assumptions of Proposition 7.4, we have

$$\chi_1 = \begin{cases} -1 & \text{if } u = w, \ p = q, \text{ and } D = N_{w,P} = A_0, \\ 0 & \text{otherwise.} \end{cases}$$

**Proof.** The fan $C_w \cap C_q = C_{N_{w,Q}}$ (Proposition 2.3) is convex and closed and is nonempty (because it contains $\sigma_{A_0}$). Therefore, $C_{N_{w,Q}}$ is either the trivial simplicial complex $\{\emptyset\}$ (when $N_{w,P} = A_0$) or a topological ball (otherwise). Hence

$$\chi_1 = \begin{cases} -1 & \text{if } N_{w,Q} = A_0, \\ 0 & \text{otherwise.} \end{cases} \quad (7.3)$$

In fact we can sharpen this statement by incorporating the locality assumptions. First, by (⋆), we can replace the condition $C_w \cap C_q = \{A_0\}$ with $C_w \cap C_q = \{A_0\}$. For this to happen, it is necessary that $q = p$. Moreover, since $D \in C_Q$ by assumption (⋆⋆), the case $\chi_1 = -1$ occurs only when $D = A_0$, or equivalently $u = w$. \hfill □

**Remark 7.10.** The conditions $q = p$ and $u = w$ are not sufficient to imply $\chi_1 = -1$ (see Example 7.20), although the three conditions $q = p, u = w,$ and $\dim p = n - 1$ together are sufficient.

**Proposition 7.11.** Under the locality assumptions of Proposition 7.4, we have

$$\chi_2 = \begin{cases} (-1)^{\des(u \cap w)} & \text{if } u \neq w \text{ and } D = N_{w,Q}, \text{ and } C_q \cap C_w \neq \emptyset, \\ 0 & \text{otherwise.} \end{cases}$$

**Proof.** There are three cases to consider.
(1) If $|D| = 1$ (i.e., $D = A_0$), then $\mathcal{F} = \emptyset$ and clearly $\chi_2 = 0$. Therefore, in the remaining cases, we assume henceforth that $|D| > 1$, or equivalently $u \neq w$.

(2) If $C_q$ contains a star point of $\mathcal{F}$ other than the origin — that is, if it contains some cone $\sigma_A$ such that $A_0 \neq A \leq W$ and $A \wedge D = A_0$ — then that point is also a star point of $\mathcal{F} \cap C_q$. Therefore, intersecting with $\Sigma^{n-2}$ produces a topological ball, whose reduced Euler characteristic $\chi_2$ vanishes. (This case occurs only when $1 < |D| < n$.)

(3) Suppose that $C_q$ contains no star point of $\mathcal{F}$. That is, no cone $\sigma_A \in \mathcal{F} \cap C_q$, other than $\sigma_{A_0}$, satisfies $A \wedge D = A_0$. But in particular this is true when $\sigma_A$ is a ray in $C_q$, so in fact $C_q \cap C \subseteq [A_0, \sigma_D] = C_D$ and then equality holds by assumption (**). Since $\mathcal{F}$ contains every cone in $C_D$ other than $\sigma_D$ itself, it follows that $\mathcal{F} \cap C_q = C_D \backslash \{\sigma_D\} = \partial C_D$ and therefore $\chi_2 = -(1)^{\dim \sigma_D} = (-1)^{\text{des}(w^{-1}u)}$ by (2.18).

Now rewriting the results of the case analysis combinatorially gives the desired formula for $\chi_2$. (The first locality assumption * was not used, so it needs to be included in the first case of the formula.)

\[ \chi_2 = \begin{cases} 
(\chi(\mathcal{G})) & \text{if } D \in \partial C_Q \text{ and } C_Q \cap C_W \neq \emptyset \\
0 & \text{otherwise},
\end{cases} \]

where $\mathcal{G} = \mathcal{G}(Q, w, u)$ is a certain Scrope complex (to be constructed in the proof).

**Proof.** Recall that $\chi_3 = \sum_{A \in G} (-1)^{|A|}$, where $G = G(Q, w, u) = E \cap \partial C_Q$. By Lemma 2.5 and Prop. 2.3, we have

\[ G = \{ A \in C_Q : D \leq A \leq W \text{ and } A \text{ collapses some relation of } Q \} = \{ A \in \text{Comp}(I) : D \leq A \leq N \text{ and } A \text{ collapses some relation of } Q \} \tag{7.4} \]

where $N = N_{w,Q}$ is the $w$-naturalization of $Q$ (see §2.3). Now, given a pair $c_i, d_i \in I$ such that $c_i <_Q d_i$ and $c_i \equiv_D d_i$, let $N_{x_i}$ and $N_{y_i}$ be the blocks of $N$ containing $c_i$ and $d_i$ respectively (so that $x_i < y_i$), and let

\[ S_i = N_1 \mid \cdots \mid N_{x_i-1} \mid N_{x_i} \cup \cdots \cup N_{y_i} \mid N_{y_i+1} \mid \cdots \mid N_k. \]

Then $S_i \in G$ by (7.4). Moreover, every composition in $G$ is refined by or equal to some $S_i$. In other words,

\[ G = \bigcup_{i=1}^r [D, S_i]. \]

The maximal Boolean intervals $[D, S_i]$ of this form are those for which the integer interval $[c_i, d_i]$ is minimal; in this case we call $c_i <_Q d_i$ a short relation. Thus in computing $G$ it suffices to consider only short relations.

As usual, let us identify every set composition in $[D, W]$ with the simplex on its separators (by passing to braid cones and intersecting with $S^{n-2}$, as in §2.3). Then the simplicial complex $\mathcal{G} = \mathcal{G}(Q, w, u)$ corresponding to $G$ is a Scrope complex whose vertices correspond to the separators between blocks of $N$; specifically, $\mathcal{G} \cong \text{Scr}(k, z)$, where $z = ((x_1, y_1), \ldots, (x_r, y_r))$. It follows that $\chi_3 = (-1)^{|D|-1} \chi(\mathcal{G}) = (-1)^{\text{des}(w^{-1}u)} \chi(\mathcal{G}) \in \{0, -1, 1\}$, as desired.

For the locality assumptions, note that $D \in \partial C_Q$ directly implies (**). Condition (*) did not arise in the calculation, so it is incorporated directly into the formula for $\chi_3$. \[ \square \]
Example 7.13. Let \( w = u = 12345678 \) (as linear orders) so that \( D = A_0 = 12345678 \). Let \( Q \) be the \( w \)-natural preposet shown below, so that that \( N = 1\mid 234\mid 567\mid 8 \).

\[
\begin{array}{c}
567 & 8 \\
\mid & \mid \\
234 & \\
\mid & \\
1 & \\
\end{array}
\]

The compositions \( A \) such that \( D \trianglelefteq A \trianglelefteq N \) are

\[
\begin{align*}
1\mid 2345678 & \quad 1\mid 2345678 & \quad 1\mid 2345678 & \quad 1\mid 2345678 \\
1\mid 2345678 & \quad 1\mid 2345678 & \quad 1\mid 2345678 & \quad 1\mid 2345678
\end{align*}
\]

where each of the short relations \( 1 <_Q 2 \) and \( 3 <_Q 5 \) is marked whenever it occurs in a block. Thus the last two compositions listed do not belong to \( G \). Moreover,

\[
G = [D, S_{12}] \cup [D, S_{35}]
\]

whose geometric realization is shown below. Note that \( \tilde{\chi}(G) = 0 \).

Proposition 7.14. The formula \( a^\mu_{u,q} \) is multiplicity- and cancellation-free. That is, each of the terms \( \chi_1, \chi_2, \chi_3 \) is 0, 1, or \( -1 \), and at most one of them is nonzero.

Proof. First, suppose that \( \chi_1 \neq 0 \). Then by Proposition 7.9 \( u = w \) (so \( D = A_0 \)) and \( p = q \).

It follows from Proposition 7.11 that \( \chi_2 = 0 \). Moreover, the preposet \( Q \) has no proper relations, so \( G = \emptyset \) and \( \chi_3 = 0 \).

Second, suppose that \( \chi_1 = 0 \) and \( \chi_2 \neq 0 \). Then \( D \in C_Q \), but then \( D \notin \partial C_Q \) and so \( \chi_3 = 0 \).

By Proposition 7.14, we can combine Propositions 7.9, 7.11, and 7.12 into a single formula for the coefficients of the antipode:

\[
a^\mu_{u,q} = \begin{cases} 
-1 & \text{if } u = w, p = q, \text{ and } D = N_{w,p} = A_0, \\
-(-1)^{\text{des}(u^{-1}w)} & \text{if } D \neq A_0 \text{ and } D = N_{w,p}, \text{ and } C_W \cap C_Q \neq \emptyset, \\
-(-1)^{\text{des}(u^{-1}w)}\tilde{\chi}(\mathcal{G}(Q, w, u)) & \text{if } D \in \partial C_Q \text{ and } C_W \cap C_Q \neq \emptyset, \\
0 & \text{otherwise}. 
\end{cases}
\]

We can finally write down a combinatorial formula for the antipode in \( \text{OGP}_+ \):

\[
s(w \otimes p) = -\xi w \otimes p - \sum_{(u,q) \in \mathcal{L}_+[\mathcal{L}_+[w]] \times \tilde{\chi}(p): \ D = N_{w,p}, \ C_W \cap C_Q \neq \emptyset} (-1)^{\text{des}(u^{-1}w)} u \otimes q
\]

\[
- \sum_{(u,q) \in \mathcal{L}_+[\mathcal{L}_+[w]] \times \tilde{\chi}(p): \ D \in \partial C_Q, \ C_W \cap C_Q \neq \emptyset} (-1)^{\text{des}(u^{-1}w)} \tilde{\chi}(\mathcal{G}(Q, w, u)) u \otimes q
\]

(7.5)
where $\xi$ is 1 if $C_W \cap C_P = \{A_0\}$ and 0 otherwise. (In particular, $\xi = 1$ if $p$ has full dimension $|I| - 1$.)

In fact this expression can be simplified. Suppose we extend the range of summation for $u$ in the first sum from $I_p[I] \setminus \{w\}$ to $I_p[I]$. If $u = w$, then $D = A_0$ and $C_D = \{A_0\}$, so $C_W \cap C_Q = C_D$ if and only if $A_0 \in C_Q$, i.e., $q = p$ and $\xi = 1$. Therefore, we can absorb the term $-\xi w \otimes p$ into the first sum to obtain the final result, as follows.

**Theorem 7.15.** The antipode in OGP is given by the formula

$$s(w \otimes p) = \sum_{(u,q) \in I_p[I] \times G(p): D = N, \emptyset \neq C_W \cap C_Q} (-1)^{1+\text{des}(u^{-1}w)} u \otimes q + \sum_{(u,q) \in I_p[I] \times G(p): D \in \partial C_Q, \emptyset \neq \emptyset} (-1)^{1+\text{des}(u^{-1}w)} \tilde{\chi}(G) u \otimes q$$

where $\tilde{G} = \tilde{G}(Q, w, u)$ is the Scrope complex defined above.

**Remark 7.16.** Recall that summing over all $w \in S_n$ produces the much simpler expression (4.6). It is not immediately clear why so much cancellation occurs in that symmetrization.

**Remark 7.17.** It is tempting to try to combine $s_1$ and $s_2$ into a single sum. To accomplish this, it is necessary to understand the Scrope complex $\tilde{G}(Q, w, u)$ in the case $D = N$. By (7.4), if $N \in \partial C_Q$ then $G = \{N\}$, while if $N \in C_Q$ then $G = \emptyset$. But in the first of those cases the condition $C_W \cap C_Q \neq \emptyset$ fails, while in the second case $\chi(G) = \chi(\emptyset) = 0$, not 1, so the sums cannot be combined.

**Remark 7.18.** The expression $s_2$ may contain some zero summands, since Scrope complexes can be contractible. However, it is not clear how to predict when this will happen. It would be helpful to have a non-recursive way of determining the topology of a Scrope complex. On the other hand, when $D \in \partial C_Q$ is a maximal element, then the corresponding Scrope is the trivial complex, whose Euler characteristic is nonzero. So $s_2$ is nonzero.

**Example 7.19.** The sign of a term $u \otimes q$ in $s(w \otimes p)$ may depend on $u$ as well as on $q$. For example, let $p$ be the three-dimensional cone of Example 2.6. This cone has a unique vertex $q = (1, 2, 3, 4)$, whose normal cone $C_q$ is the union of three braid cones (see Figure 1). Let $w = 1234$. The intersection $\partial C_q \cap C_w$ has two maximal elements, the vertex $1|234$ and the edge $12|34$. Hence

- If $u = 2341$, then $D(w, u) = 1|234 \in C_q \cap C_w$ and $(-1)^{1+\text{des}(u^{-1}w)} \tilde{\chi}(\tilde{G}) = 1$.
- If $u = 4312$, then $D(w, u) = 12|34 \in C_q \cap C_w$ and $(-1)^{1+\text{des}(u^{-1}w)} \tilde{\chi}(\tilde{G}) = -1$.

**Example 7.20.** We give an example of an antipode calculation for an unbounded polytope. Let $p$ be the segment $\text{conv}\{(1, 0, 0), (0, 1, 0)\}$, and let $p'$ be the ray with vertex $(0, 1, 0)$ and direction $(1, -1, 0)$. Thus $p' \supset p$, and in fact the normal fan $\mathcal{N}_{p'}$ is a non-complete subfan of $\mathcal{N}_p$, as shown below.

The computation of $s(w \otimes p)$ is shown in the table below. If $p'$ is bounded in the direction given by $w$ (that is, if the braid cone $\sigma_w$ appears in $\mathcal{N}_{p'}$), then the computation of $s(w \otimes p')$ is identical to that of $s(w \otimes p)$, replacing $p$ with $p'$. Note that the point $a$, which is a face of
but not of \( p' \), does not appear in these cases.

<table>
<thead>
<tr>
<th>( w )</th>
<th>( \chi_1 )</th>
<th>( \chi_2 )</th>
<th>( \chi_3 )</th>
<th>( p' ) bounded?</th>
</tr>
</thead>
<tbody>
<tr>
<td>123</td>
<td>0</td>
<td>(132 + 312) ( \otimes ) ( p ) − 321 ( \otimes ) ( b )</td>
<td>(−132 − 312) ( \otimes ) ( b )</td>
<td>Yes</td>
</tr>
<tr>
<td>132</td>
<td>−132 ( \otimes ) ( p )</td>
<td>−231 ( \otimes ) ( b )</td>
<td>+132 ( \otimes ) ( b )</td>
<td>Yes</td>
</tr>
<tr>
<td>312</td>
<td>0</td>
<td>(123 + 132) ( \otimes ) ( p ) − 213 ( \otimes ) ( b )</td>
<td>(−123 − 132) ( \otimes ) ( b )</td>
<td>Yes</td>
</tr>
<tr>
<td>321</td>
<td>0</td>
<td>(213 + 231) ( \otimes ) ( p ) − 123 ( \otimes ) ( a )</td>
<td>(−213 − 231) ( \otimes ) ( a )</td>
<td>No</td>
</tr>
<tr>
<td>231</td>
<td>−231 ( \otimes ) ( p )</td>
<td>−132 ( \otimes ) ( a )</td>
<td>+231 ( \otimes ) ( a )</td>
<td>No</td>
</tr>
<tr>
<td>213</td>
<td>0</td>
<td>(231 + 321) ( \otimes ) ( p ) − 312 ( \otimes ) ( a )</td>
<td>(−231 − 321) ( \otimes ) ( a )</td>
<td>No</td>
</tr>
</tbody>
</table>

Observe that each row is itself cancellation-free, and that adding rows together recovers the symmetrized formulas

\[
\sum_{w \in \mathcal{E}_3} s(w \otimes p) = \sum_{w \in \mathcal{E}_3} w \otimes (p - a - b)
\]

and

\[
\sum_{w \in \mathcal{N}_p} s(w \otimes p') = \sum_{w \in \mathcal{N}_p} w \otimes p' - \sum_{w \in \mathcal{E}_3} w \otimes b
\]

confirming (4.6) in this case.

8. Special cases of the antipode

In this section, we specialize the antipode formula of Theorem 7.15 to several natural families of OGPs: standard permutohedra, hypersimplices, and zonotopes of star graphs.
We discuss the difficulties involved in calculating the antipode for other families, including general graphical zonotopes and matroid complexes. Throughout, we fix the ground set \( I = [n] \), so that we can identify orderings in \( \ell[I] \) with permutations in \( \mathfrak{S}_n \).

### 8.1. The standard permutohedron

Let \( p = \Pi_{n-1} \subset \mathbb{R}^{[n]} \) be the standard permutohedron (see §2.4) and let \( w \in \mathfrak{S}_n \). The normal fan of \( \Pi_{n-1} \) is exactly the braid fan, so its faces \( q = p_Q \) are labeled by ordered set partitions \( Q \), and every \( C_Q \) is a principal order ideal (in fact a Boolean interval) in \( \text{Comp}(n) \). We compute the antipode of \( w \otimes \Pi_{n-1} \) using Theorem 7.15.

1. Since \( Q \) must be \( w \)-natural in order to show up in the antipode (Corollary 7.5), the condition \( C_W \cap C_Q = C_D \) becomes simply \( C_Q = C_D \), or \( Q = D \). Therefore, the first sum in Theorem 7.15 becomes

\[
\sum_{u \in C_Q, D(w,u) = Q} (-1)^{\text{des}(u^{-1}w)} u \otimes p_Q = \sum_{u \in D(w,u) = Q} (-1)^{|Q|} u \otimes p_Q.
\]

2. The condition \( D(w,u) \in \partial C_Q \) is equivalent to \( D(w,u) \prec Q \). Since \( Q \) is an ordered set partition, we have \( Q = N \), so \( G = \{ A : D \subseteq A \prec Q \} \), which is a Boolean interval with its top element missing. Therefore \( \tilde{\mathcal{G}} = \tilde{\mathcal{G}}(Q, w, u) \) is the boundary of a simplex of dimension \(|Q| - |D| - 1 = |Q| - \text{des}(w^{-1}) - 2 \) and so \( \chi(\tilde{\mathcal{G}}) = (-1)^{|Q| - \text{des}(w^{-1})} \). So the second sum in Theorem 7.15 becomes

\[
\sum_{u \in C_Q, D(w,u) \prec Q} (-1)^{|Q| - \text{des}(u^{-1})} u \otimes p_Q = \sum_{u \in D(w,u) \prec Q} (-1)^{|Q|} u \otimes p_Q.
\]

Putting the two sums together gives

\[
s(w \otimes \Pi_{n-1}) = s_1 + s_2 = \sum_{Q \text{ w-natural}} (-1)^{|Q|} \sum_{u : D(w,u) \subseteq Q} u \otimes p_Q.
\]

The condition \( D(w,u) \subseteq Q \) is equivalent to \( \text{Des}(w^{-1}w) \subseteq \{ |Q_1|, |Q_1| + |Q_2|, \ldots, |Q_1| + \cdots + |Q_{k-1}| \} \), where \( Q = Q_1 \cdots Q_k \). See [Sta12, §1.4] for more information about enumerating permutations according to their descent set.

### 8.2. Spider preposets

For our next two examples of antipodes in \( \text{OGP}_+ \), we need the following family of preposets.

**Definition 8.1.** Let \( A, B \) be disjoint subsets of \( I \). The corresponding **spider** \( Q = Q(A,B) \) is the preposet on \( I \) such that \( C = C(Q) = \Gamma \setminus (A \cup B) \) is a block of \( Q \) (called the **center**), and every other element is a singleton block; \( C \) lies above the singletons in \( A \) and below the singletons in \( B \).

Let \( w \) be a linear order on \([n]\) such that \( Q \) is \( w \)-natural. Equivalently, \( A \) and \( B \) are respectively initial and final segments of \( w \); that is, \( A = \text{ini}_k(w) = \{ w(1), \ldots, w(k) \} \) and \( B = \text{fin}_k(w) = \{ w(n - \ell - 1), \ldots, w(n) \} \). For the purpose of the antipode formula, we need to understand the poset \( \partial C_Q \cap C_W \).
Write $A = \{a_1, \ldots, a_k\}$ and $B = \{b_1, \ldots, b_\ell\}$, with elements indexed according to their order in $w$. Define set compositions

$$
N_Q = a_1 | \cdots | a_{k-1} \mid a_k \mid C \mid b_1 \mid b_2 \mid \cdots \mid b_\ell,
$$

$$
N^a_Q = a_1 | \cdots | a_{k-1} \mid a_k \cup C \mid b_1 \mid b_2 \mid \cdots \mid b_\ell,
$$

$$
N^b_Q = a_1 | \cdots | a_{k-1} \mid a_k \mid C \cup b_1 \mid b_2 \mid \cdots \mid b_\ell,
$$

$$
N^{ab}_Q = a_1 | \cdots | a_{k-1} \mid a_k \cup C \cup b_1 \mid b_2 \mid \cdots \mid b_\ell.
$$

Here $N_Q$ is the same set composition defined in the proof of Proposition 7.12; moreover, $\partial C_Q \cap C_W$ is the order ideal of $\text{Comp}(n)$ generated by $N^a_Q$ and $N^b_Q$. In all cases, the interval $[N^{ab}_Q, N_Q] = \{N^{ab}_Q, N^a_Q, N^b_Q, N_Q\}$ is Boolean; however, if one or more of $A, B, C$ is empty, then some of these set compositions coincide. For reference, the various cases are shown in Figure 6.

![Figure 6](image.jpg)

**Figure 6.** Possibilities for the interval $[N^{ab}_Q, N_Q]$.

If two or more of $A, B, C$ vanish, then $N_Q = N^a_Q = N^b_Q = N^{ab}_Q$.

**Lemma 8.2.** Let $Q = Q(A, B)$ be a spider on $[n]$ and $w$ a linear order on $[n]$ such that $Q$ is $w$-natural. Let $u \in \mathfrak{S}_n$ and $D = D(w, u)$, and $\tilde{G} = \tilde{G}(q, w, u)$, as constructed in the proof of Proposition 7.12. Then

$$
\tilde{\chi}(\tilde{G}) = \begin{cases} 
(-1)^{|Q| - |D|} & \text{if } N^{ab}_Q \preceq D \prec N_Q, \\
0 & \text{otherwise.}
\end{cases}
$$

**Proof.** If at least two of $A, B, C$ are empty, then $\tilde{G}$ is the void complex, with reduced Euler characteristic 0. Meanwhile, the interval $[N^{ab}_Q, N_Q]$ is trivial, so the condition $N^{ab}_Q \preceq D \prec N_Q$ is impossible.

If $A = \emptyset$ and $B, C \neq \emptyset$, then $Q$ has one short relation, namely $C \prec Q b_1$, so $\tilde{G} \simeq [D, N^b_Q]$, which is either a simplex or void (hence has reduced Euler characteristic zero) unless $D = N^b_Q = N^{ab}_Q$. In this case $\tilde{G}$ is the trivial complex, with reduced Euler characteristic 1. The case that $B = \emptyset$ and $A, C \neq \emptyset$ is analogous.

Similarly, if $C = \emptyset$ and $A, B \neq \emptyset$, then again $Q$ has one short relation, namely $a_k \prec Q b_1$, so $\tilde{G} \simeq [D, N^{ab}_Q]$, whose Euler characteristic is 1 if $D = N^{ab}_Q$ and 0 otherwise.

Finally, suppose that $A, B, C$ are all nonempty. Then $Q$ has two short relations, namely $a_k \prec Q C$ and $C \prec Q b_1$. Thus the face poset of $\tilde{G}$ is isomorphic to $[D, N^a_Q] \cup [D, N^b_Q] \subseteq \text{Comp}(n)$. The cases are as follows:
• If $D = N_Q^a$ then $\mathcal{G} \cong S_0^r$, whose reduced Euler characteristic is $+1$.
• If $D = N_Q^b$ or $S = N_Q^b$, then $\mathcal{G}$ is the trivial complex, with reduced Euler characteristic $-1$.
• If $D$ coarsens exactly one of $N_Q^a$ or $N_Q^b$, then the face poset is Boolean of positive rank, so $\mathcal{G}$ is a simplex, hence contractible.
• If $D \triangleleft N_Q^b$, then $\mathcal{G}$ is the union of two simplices that intersect in a common subface, so again it is contractible.
• Otherwise, $\mathcal{G}$ is the void complex.

Thus the claimed formula holds in all cases. □

8.3. Hypersimplices. For positive integers $n > r$, the $(n, r)$ hypersimplex is defined as the polytope

$$\Delta(n, r) = \left\{ (x_1, \ldots, x_n) \in [0, 1]^n : \sum_{i=1}^n x_i = r \right\}.$$  

The hypersimplex is the matroid base polytope of the uniform matroid of rank $r$ on $n$ ground elements; in particular, it is a generalized permutohedron of dimension $n - 1$. Its vertices are the vectors $(x_1, \ldots, x_n)$ with exactly $r$ entries equal to 1 and the rest equal to zero. In particular, $\Delta(n, 0)$ is a point and $\Delta(n, 1)$ is the standard simplex, and the polytopes $\Delta(n, r)$ and $\Delta(n, n - r)$ are congruent.

It is not hard to describe and count the faces of a hypersimplex, but we have been unable to find an explicit statement in the literature, so we give a short proof here.

Proposition 8.3. The faces of $\Delta(n, r)$ are precisely the polytopes

$$q(A, B) = \{(x_1, \ldots, x_n) \in \Delta(n, r) : x_a = 0 \forall a \in A, \ x_b = 1 \forall b \in B\} \quad (8.2)$$

where $A, B$ are disjoint subsets of $[n]$ such that either $|A| = n - r$ and $|B| = r$ (when $q(A, B)$ is a vertex) or $|A| < n - r$ and $|B| < r$ (when $\dim q(A, B) = n - 1 - |A| - |B|$). Consequently, the number of $d$-dimensional faces is

$$f_d(\Delta(n, r)) = \binom{n}{d}, \quad f_d(\Delta(n, r)) = \binom{n}{d} \sum_{k=d}^{r-1} \binom{n-d-1}{k} (1 \leq d \leq n - 1).$$

Proof. Let $\lambda(x_1, \ldots, x_n) = \lambda_1 x_1 + \cdots + \lambda_n x_n$ be a linear functional on $\mathbb{R}^n$. Without loss of generality, suppose $\lambda_1 \leq \cdots \leq \lambda_n$. If $\lambda_r < \lambda_{r+1}$ then $\lambda$ is maximized uniquely at the vertex $q([1, n - r], [n - r + 1, n])$. Otherwise, let $i, j$ be such that $\lambda_i < \lambda_i + 1 = \cdots = \lambda_{n-r} = \lambda_{n-r+1} = \cdots = \lambda_{j-1} < \lambda_j$. Then $\lambda$ is maximized at the vertices in $q([1, i], [j, n])$, and $|[1, i]| < n - r$ and $|[j, n]| < r$. □

The normal preposet of $q(A, B)$ is the spider $Q(A, B)$ of Definition 8.1.

For $w \in \mathcal{S}_n$, the spider $Q(A, B)$ is $w$-natural if and only if $A$ and $B$ are initial and final segments of $w$, say $A = \text{ini}_i(w)$ and $B = \text{fin}_j(w)$. In this case we write $Q(A, B) = Q_{k, \ell}^w$, and we also write $q_{k, \ell}^w$ for the corresponding face of $\Delta(n, r)$. By Corollary 7.5, the $q_{k, \ell}^w$ are the only faces occurring in the antipode of $w \otimes \Delta(n, r)$. This is a strong restriction; for instance, the only vertex that can occur is $v = q_{n-r, r}$. For $\Delta(4, 2)$ and $w = [1234]$, the $w$-natural faces are those indicated in Figure 5.
Theorem 8.4. Let \( w \in \ell[I] = \mathfrak{S}_n \). Then
\[
s(w \otimes \Delta(n, r)) = \sum_{k, \ell} \sum_{u \in \ell[I]} \sum_{N_Q^k \leq D(u, w) \leq N_Q} u \otimes (-1)^{n-\dim q} q
\]
where either \((k, \ell) = (n-r, r)\), or else \(0 \leq k < n-r \) and \(0 \leq \ell < r\); \(Q = Q_{k,\ell}^r\) and \(q = q_{k,\ell}^r\).

The proof is the same as in Theorem 8.4.

Proof. In \( s_1 \) we have \( D = N_Q \), so that \( \text{des}(u^{-1}w) + 1 = |D| = |N_Q| = |Q| = n - \dim q \). Meanwhile, by Lemma 8.2, the summand in \( s_2 \) vanishes unless \( D \in \{N^a_Q, N^b_Q, N^{ab}_Q\} \), all of which belong to \( \partial C_Q \). Therefore, Theorem 7.15 boils down to
\[
s(w \otimes \Delta(n, r)) = \sum_{k, \ell} \sum_{D(w, u) = N_Q} (1 + \dim q) u \otimes q + \sum_{k, \ell} \sum_{N_Q^k \leq D(w, u) \leq N_Q} (1 - |D|) (1 - |Q|) u \otimes q,
\]
and combining the two sums and rewriting in terms of \( q \) gives the theorem. \qed

8.4. Zonotopes of stars. Let \( G \) be a simple graph on vertex set \([n]\). The corresponding graphical zonotope is the Minkowski sum \( \sum_{ij} s_{ij} \), where \( ij \) ranges over all edges of \( G \) and \( s_{ij} \) is the line segment from \( e_i \) to \( e_j \). There does not appear to be a combinatorial formula for the antipode of an ordered graphic zonotope, since we lack a general description of the preposets corresponding to normal cones of faces. However, in the following special case, we can give an explicit formula. Let \( G = \text{St}(n, c) \) be the star graph with center vertex \( c \) and leaves \([n]\setminus\{c\} \), for some \( c \in [n] \), so that the corresponding zonotope is
\[
j_{n,c} = \sum_{i \neq c} s_{ic} = \left\{ (x_1, \ldots, x_n) \in \mathbb{R}^n : \sum_{i=1}^n x_i = n-1, \quad 0 \leq x_j \leq 1 \quad \forall j \neq c \right\}, \tag{8.3}
\]
which is a parallelepiped. The faces of \( j_{n,c} \) are precisely the polytopes
\[
q(A, B) = \left\{ (x_1, \ldots, x_n) \in j_{n,c} : x_a = 0 \quad \forall a \in A, \quad x_b = 1 \quad \forall b \in B \right\}
\]
where \( A, B \) are disjoint subsets of \([n]\setminus\{c\} \). We reuse the notation of the previous example because, as before, \( \dim q(A, B) = n-1 - |A| - |B| \), and the normal preposet of \( q(A, B) \) is the spider \( Q(A, B) \) of Definition 8.1; the spiders that arise are precisely those whose center contains \( c \).

Theorem 8.5. Let \( w \in \ell[I] = \mathfrak{S}_n \). Then
\[
s(w \otimes j(n, c)) = \sum_{k, \ell} \sum_{u \in \ell[I]} \sum_{N_Q^{ab} \leq D(w, u) \leq N_Q} u \otimes (-1)^{n-\dim q} q
\]
where \( k, \ell \) are nonnegative integers with \( k \leq w^{-1}(c) - 1 \) and \( \ell \leq n - w^{-1}(c) \), and \( q = q_{k,\ell} \).

Proof. The proof is the same as in Theorem 8.4 mutatis mutandis. \qed

In general, an explicit antipode formula for a class of generalized permutohedra requires a description of their normal fans in terms of preposets, as well as an understanding of the Scrope complexes that arise in the \( s_2 \) piece of Theorem 7.15. For this reason, it is
probably intractable to ask for a formula for a class as large as all matroid polytopes, for instance.

9. Open Questions

(1) Is there a closed formula for the Euler characteristic of a Scrope complex? For individual examples it can be calculated efficiently using Proposition 7.2, but for the purpose of simplifying antipode calculations it would be better to have a non-recursive combinatorial condition in terms of the intervals that define facets. What else can be said about Scrope complexes?

(2) A character on a Hopf monoid $H$ is essentially a multiplicative function: a collection of linear maps $\zeta : H[I] \to \mathbb{C}$ such that $\zeta(x \cdot y) = \zeta(x)\zeta(y)$; see [AA17, §8] for details. Ardila and Aguiar used character theory on $GP$ and its submonoids for numerous applications, including formulas for multiplicative and compositional inverses of power series, polynomial invariants of Hopf monoids. What are the parallel results for $OGP_+$ and its submonoids?

(3) Further refine the hierarchy of Hopf classes described in Figure 2 (§3.3). In particular, resolve Conjectures 3.14 and 3.15.

(4) What can be said about Hopf classes containing non-prefix-pure complexes (hence, containing non-pure complexes)?

(5) Recall (§5) that $Mat_+$ is the class of pure simplicial complexes whose facets are the supports of vertices of some extended (i.e., possibly unbounded) generalized permutohedron. What can we say about these complexes? What properties, if any, do they share with matroid complexes? Is there a result analogous to the characterization [GGMS87, Thm. 4.1] of matroid polytopes as the generalized permutohedra that are 0/1-polytopes?

(6) For which Hopf classes can we obtain a cancellation-free formula for the antipode in the corresponding Hopf monoid? When is the antipode multiplicity-free, or equivalently, when do the albums $C_{i_1}^\otimes$ defined in (6.3) have always “Euler characteristic” in $\{0, \pm 1\}$? (This is Conjecture 6.1.)

(7) For what other families of ordered generalized permutohedra, other than those studied in §8, does the general antipode formula (Theorem 7.15) simplify nicely? Families of interest include associahedra and nestohedra; see [PRW08]. As mentioned at the end of §8, it is necessary to know their normal fans explicitly and to understand which Scrope complexes arise in the antipode.

(8) The Hopf class $OMAT$ of ordered matroids is geometric, in the sense that mapping every matroid to its base polytope gives an embedding $OMat = OMAT^3 \to OGP_+$. For which other Hopf classes is there a comparable geometric embedding? Of particular interest is the Hopf class $BC$ of broken-circuit complexes (see Example 3.12), in light of their crucial role in the recent work of Ardila, Denham, and Huh [ADH20]. Is there a maximal Hopf class that embeds in $OGP_+$, and if so, can it be characterized in purely combinatorial terms? Aguiar and Ardila’s universality theorem for $GP$ [AA17, Theorem 6.1] implies that any such embedding necessarily involves polyhedra that are either unbounded or contain vertices that are not 0/1 vectors.
(9) Extend OGP to a Hopf monoid of fans that coarsen the braid arrangement, but are not necessarily polytopal. See [PRW08, Example 3.8].

(10) The basis elements of $L^*$ are permutations, which correspond to maximal cones in the braid fan. We know that the antipode of an element $w \otimes p$ of $OGP_+ = L^* \times GP_+$ “sees” the local geometry of $p$ near the vertex maximized by $w$. Can we replace $L^*$ with some Hopf monoid $H$ of set compositions (which correspond to all braid cones), so that the antipode of $A \otimes p$ in the resulting Hadamard product $H \times GP_+$ is local with respect to the face of $p$ maximized by $A$? Aguiar and Mahajan [AM10, §§12.4–12.5] describe a dual pair of Hopf monoids $\Sigma, \Sigma^*$ of set compositions and give explicit antipode formulas; there are maps $L \to \Sigma$ and $\Sigma^* \to L^*$ [AM10, Thm. 12.57] arising from the inclusion of permutations into set compositions.

(11) While the antipode of an element $w \otimes p \in OGP_+$ can be very complicated, we know that symmetrizing by summing over all $w$ produces the much nicer formula (4.6). What about the “partial symmetrization” obtained by summing over all permutations minimizing some fixed vertex of $p$?

(12) It is tempting to try to construct a Hopf monoid on Coxeter matroids, or more generally on Coxeter generalized permutohedra [ACEP20]. The main obstacle is that equation (2.8), which is essential to define the coproduct, no longer holds. In fact [AA17, Theorem 6.1] seems to close the door on considering a larger family of polytopes, so some new idea is called for.

(13) We have two cancellation-free formulas for the antipode of an ordered shifted (Schubert) matroid (see §6.3). One is the general formula (6.13) for shifted complexes (or more compactly Theorem 6.3 when there are no loops or coloops). The other formula arises from Theorem 7.15, because matroid base polytopes are generalized permutohedra. What can we learn about shifted matroids by comparing these two formulas? More generally, what can we learn about an arbitrary shifted complex by comparing its antipode (using (6.13)) with that of its matroid hull (using Theorem 7.15)?

(14) The Hopf morphism $\tilde{\Upsilon} : OIGP_+ \to OMat_+$ described in Proposition 5.3 is surjective (by definition), but not injective. What is its kernel? What can be said about 0/1 extended generalized permutohedra with the same indicator complex (whether or not it is a matroid complex)?

(15) Ardila and Sanchez [AS20] recently studied valuations of generalized permutohedra by passing to a quotient of $GP_+$ by inclusion/exclusion relations, as in McMullen’s polytope algebra [McM89]. They showed that this quotient is isomorphic to a Hopf monoid of weighted ordered partitions. One could look for an ordered analogue of their results, perhaps with a view toward a notion of valuations compatible with linear orders.

**Acknowledgements**

Part of this project was carried out while the third author was a postdoc at ICERM, the University of Miami and the Max-Planck Institute for Mathematics in the Sciences. He wishes to thank all the institutions for providing excellent research environments. We thank Marcelo Aguiar for helping us understand the language of Hopf monoids; Isabella Novik for supporting a weeklong meeting between the second and third authors in 2015,
where this project started (in a very different guise); and Mark Denker for numerous helpful comments on the manuscript.
